Russell’s theory of ‘definite descriptions,’ first articulated in his classic paper ‘On denoting’ (1905), paradigmatically illustrates Russell’s methodological reliance on logical analysis in addressing questions about meaning. The argument of the paper involves, among other things, the defense of a principle that Russell regarded as fundamental to the account of linguistic understanding. In *The problems of philosophy*, Russell gave the following succinct statement of the principle: “Every proposition which we can understand must be composed wholly of constituents with which we are acquainted” (1910: 32). At the time of ‘On denoting,’ Russell meant by a ‘proposition,’ roughly, the state of affairs that is expressed by an indicative sentence, whether or not that state of affairs actually obtains. A proposition’s ‘constituents’ are the real-world entities that figure in the state of affairs (or *would* figure in it, were the state of affairs to obtain). So understood, a proposition is not a linguistic entity, even in the attenuated sense of a Fregean thought. A proposition is, rather, a structured entity that comprises various nonlinguistic components of the world. What characterizes Russell’s principle of acquaintance as a principle of linguistic understanding, then, is not the linguistic *nature* of propositions, but the correlativity of propositions with the indicative sentences of a language. For Russell, understanding any such sentence requires direct experiential acquaintance with the non-linguistic constituents comprised in the proposition it expresses.

In ‘On denoting’ Russell addressed problems that the principle of acquaintance ostensibly confronts in connection with ‘denoting phrases’ – i.e., phrases of the form ‘some *x*,’ ‘every *x*,’ and especially ‘the *x*’ (i.e., so-called ‘definite descriptions’). Consider the statement: ‘The author of “On denoting” was a pacifist.’ Since Russell’s principle requires acquaintance with a proposition’s constituents as a condition for linguistic understanding, it would seem that only those personally acquainted with the author of ‘On denoting’ (i.e., with Russell himself) are in a position to understand the sentence. However, this highly counterintuitive consequence only arises on the assumption that the

denoting phrase ‘the author of “On denoting”’ functions as a genuine singular term, one that singles out Russell as a *constituent* of the corresponding proposition. Russell’s account of definite descriptions challenged this assumption by arguing that the characterization of definite descriptions as singular terms arises from a mistaken account of the logical form sentences containing them. According to this mistaken analysis, the sentence ‘The author of “On denoting” was a pacifist’ is an instance of the simple subject-predicate form *Ps*, where *s* indicates the occurrence of a singular term and *P* the occurrence of a predicate. Russell maintained that sentences containing definite descriptions have a far richer logical structure than this account would suggest. On Russell’s analysis, the statement ‘The author of “On denoting” was a pacifist’ is not a simple subject-predicate statement but has the form, rather, of a multiply quantified statement:

$$\exists x((x \text{ authored 'On denoting' } \& \forall y (y \text{ authored 'On denoting' } \rightarrow y = x)) \& x \text{ was a pacifist})$$

On this analysis, the statement says: there is an *x* such that (1) *x* authored ‘On denoting,’ (2) for any *y*, if *y* authored ‘On denoting,’ then *y* = *x* (this clause serving to ensure the uniqueness implied by the use of the definite article) and (3) *x* was a pacifist. So construed, the only nonlogical components of the sentence are the descriptive predicates ‘() authored “On denoting”’ and ‘() was a pacifist,’ with no trace remaining of the putative singular term ‘the author of “On denoting”’. Therefore, beyond an implicit understanding of the mechanisms of quantification and the logical relation of identity, acquaintance with the referents of these descriptive predicates suffices for understanding the sentence. The sentence still manages to be *about* Russell since he, and he alone, satisfies the descriptive predicates (or ‘propositional functions,’ in Russell’s terminology) contained in the sentence. However, it no longer singles out Russell as a *constituent* of the corresponding proposition, thus dispensing with the worry that the principle of acquaintance would require personal acquaintance with Russell as a condition for understanding what the sentence means.

The theory of definite descriptions vividly conveys the sense in which, for Russell, the surface grammar of natural language is inadequate as a guide to the analysis of logical form. Indeed, Russell maintained that many of the metaphysical and epistemological perplexities of traditional philosophy were a direct result of conflating the grammatical forms of natural language sentences with logical forms of the propositions we manage to express in natural language. In this connection, it is important to recognize that, for Russell, logical form is not a purely linguistic notion.

We have already taken note of the fact that Russell's early philosophy treats propositions as structured complexes that array various non-linguistic components of reality. Though Russell ultimately abandoned his early theory of propositions, he never abandoned the view that reality itself exhibits varieties of structure to which the details of a suitably perspicuous logical language must answer. In his lectures on *The philosophy of logical atomism* (1918), this view takes the form of a doctrine of 'facts,' where facts are understood as real-world complexes of individual objects and the properties and relations predicable of them. On Russell's characterization, a fact is a kind of complex that is inherently apt to determine a corresponding indicative statement as true or false – that is, true when the statement affirms the fact, and false when it denies it. The kernel of Russell's atomism consists in the view that the content of any statement (of whatever order of complexity) is ultimately analyzable in terms of the constellation of logically primitive facts that determine the statement as true or false. Russell's inventory of such facts includes 'atomic facts,' in which properties and relations are predicated of metaphysically 'simple' entities, and 'general facts,' which are facts concerning *all* or *some* of a particular category of entity. Atomic facts correspond to the atomic sentences, and general facts to the quantified sentences, of a logically regimented language. All other sentences are 'molecular' in the sense that they are compounds built up from atomic sentences and quantified sentences by the application of logical connectives such as 'not,' 'and,' 'or,' and 'if ... then ...'. Though molecular sentences assert neither atomic nor general facts, their truth or falsity is nevertheless *dependent upon* such facts in the sense that a molecular sentence will be determined as true or false *as a function of* the truth or falsity of its non-molecular subsentences. For example, if '*p*' and '*q*' are atomic sentences, then the disjunction '*p* or *q*' will be true just in case one or both of '*p*' and '*q*' are true, where the truth or falsity of these subsentences is determined directly by the atomic facts to which they relate.

Russell's metaphysical view of logical form – that is, his view that logical structure is an inherent characteristic of the facts that the real world ultimately comprises – is nicely expressed in a comment from his *Introduction to mathematical philosophy*. There Russell maintains that "logic is concerned with the real world just as truly as zoology, though with its more abstract and general features" (1919: 169). At least part of Russell's motivation for this 'substantive' conception of logic consists in his abiding conviction that the structure of language (or of an ideal language, at any rate) and the structure of the world must in

some way coincide if there is to be any prospect of expressing our knowledge of the world by linguistic means. The task of giving a detailed account of this community of form between language and world was one that Russell wrestled with many times over, but which he ultimately left to the talents of his most gifted student, Ludwig Wittgenstein – the second great exponent of the philosophy of logical atomism.

Wittgenstein on Logic and Language

Of the figures we are discussing, arguably Wittgenstein (1889–1951) addressed the question of the relation between logic and language most extensively. His earliest major work, the *Tractatus logic-philosophicus*, devotes much attention to this problem. It is on this early work that we will focus here. In this work he praised Russell for discovering that the apparent logical form of a proposition need not be its real logical form. He supplemented Russell's view with the claim that the real form of a proposition is a picture of a state of affairs in the world.

Propositions, according to the *Tractatus*, are pictures of facts. The structure of a proposition mirrors the structure of the fact it represents. What a fact and the proposition that describes it have in common is their form. "The picture, however, cannot represent its form of representation; it shows it forth" (2.172). Here we see the important Tractarian distinction between *saying* and *showing*. The statement 'it is now raining' *says* something about the world. The statement 'it is either the case that it is now raining or it is not the case that it is now raining' *says* nothing about the world. It does, however, *show* the logical relations between facts. If something can be shown it cannot be said (4.1212). It follows that nothing concerning the logical relations between facts can be said.

According to the *Tractatus* "the world is the totality of facts, not of things" (1.1). That is to say, the world is not completely described by a list of all the objects that it contains. Rather, a complete description of the world would consist of all true sentences. Facts can either be atomic or compound, and correspondingly there are two types of propositions. Atomic facts are the most basic type of fact, and all atomic facts are independent of one another. Likewise, any possible set of atomic propositions could be true at the same time. This does not hold generally, as *p* and $\sim p$ (it is not the case that *p*) cannot both be true at the same time. Compound propositions are built up by *truth functions* on atomic proposition. Any operator, including the logical operators (and, or, not, ...), that takes sentences as arguments and assigns a truth value to the compound expression based only on the truth value of the arguments, is called a truth

functional operator. For instance, 'or' designates a truth function with two argument places: the truth value of the sentence 'p or q' depends only on the truth value of the sentences 'p' and 'q'. On the other hand, in the sentence 'Julius Caesar conquered Gaul before Rome fell to barbarians,' '... before ____' designates a function that takes sentences as arguments, but it is not truth functional since we need to know more than the truth value of the arguments to determine the truth value of the compound. Wittgenstein observed that all propositions are either atomic or built up by truth functions on atomic propositions. Because of this all propositions can be expressed as a truth function on a set of atomic propositions.

Statements such as all of those of the form 'p or \sim p' are tautologies: they are true no matter what the truth value of the constituents. We can know for certain that a tautology is true, but this is only because tautologies are true independently of which atomic facts turn out to be true (and because all sentences are truth functions of atomic sentences). We cannot say that the world has a certain logical structure, this can only be shown. It is tautologies that show the logical syntax of language, but tautologies say nothing. "Logical propositions describe the scaffolding of the world, or rather they present it. They 'treat' of nothing" (6.124).

Concerning sentences of natural language, Wittgenstein thought that no serious reconstruction is necessary. "In fact, all the propositions of our everyday language, just as they stand, are in perfect logical order" (5.5563). Furthermore, Wittgenstein thought that what he says about the logical structure of language must already be known by anyone who can understand the language. "If we know on purely logical grounds that there must be elementary propositions, then everyone who understands propositions in their unanalysed form must know it" (5.5562). Remember that Wittgenstein, following Russell, distinguished between the apparent logical form of a proposition and its real logical form. The logical form of natural languages is extremely complex and shrouded in conventions. "Man possesses the capacity of constructing languages, in which every sense can be expressed, without having an idea of how and what each word mean – just as one speaks without knowing how the single sounds are produced. Colloquial language is part of the human organism and is no less complicated than it. From it it is humanly impossible to gather immediately the logic of language" (4.002).

While ordinary use of natural language is in perfect logical order, philosophy arises from the abuse of natural language. Wittgenstein thinks that philosophy is nonsense because it attempts to state what cannot be said. "Most propositions and questions,

that have been written about philosophical matters, are not false, but senseless" (4.003). The view that philosophy as standardly practiced is senseless, and therefore that a radically new approach to philosophy must be developed had a profound influence on a group of philosophers who held weekly meetings in Vienna – the Vienna Circle.

Carnap and the Vienna Circle

Rudolf Carnap (1891–1970) is generally regarded as the most influential member of the Vienna circle. This group (often called the logical positivists or logical empiricists) studied Wittgenstein's *Tractatus* carefully and much of what they wrote was inspired by or was a reaction to this work. Logical positivism is often thought of as being characterized by its commitment to *verificationism*. In its strictest form, verificationism is the view that the meaning of a sentence consists in the method of its verification – that is, in the epistemic conditions under which the statement would properly be acknowledged as true. In a less strict form, it is the view that the meaning of a sentence consists of what would count as evidence for or against it. There was much debate in the circle as to what form the verificationist principle should take. There was in the circle very little objection (Gödel being the notable exception) to the thesis that there are two different kinds of statements – empirical (synthetic) and logico-mathematical (analytic) statements. Concerning empirical statements, their meaning is given by what would amount to a verification (or confirmation on a less strict view) of the statement or its negation. Concerning logico-mathematical statements, the circle was much influenced by Wittgenstein's view that tautologies are *a priori* truths – truths that are knowable independently of experience because they say nothing concerning the state of the empirical world.

What Wittgenstein counted as a logical truth (a tautology) was not sufficiently broad to include all of mathematics. Since mathematical truths are not empirical assertions, members of the Vienna circle thought they should have the same status as other logical truths. Carnap undertook to broaden the definition of logical truth so as to include all mathematical statements. To do this Carnap had to answer the question of what makes something a logical truth. Carnap's answer to this question involved the adoption of a strong form of conventionalism, which he expressed in terms of his famous 'principle of tolerance': "In logic, there are no morals. Everyone is at liberty to build up his own logic, i.e. his own form of language, as he wishes. All that is asked of him is that, if he wishes to discuss it, he must state his methods

clearly, and give syntactic rules instead of philosophical arguments" (*The logical syntax of language*, §17). This principle states that logical truth is a matter of convention. Which statements are treated as belonging to the set of analytic statements is a matter of pragmatic decision, provided that the set can be clearly defined. There is, for Carnap, no logical structure of the world that is either rightly or wrongly captured by our choice of logic. Logical relationships between sentences are a matter of stipulation on our part. However, by classifying logical statements as analytic, and therefore independent of empirical circumstances, Carnap preserves the Wittgensteinian idea that logical truths say nothing about the world. Carnap later summarized his position on logico-mathematical truth by claiming that analytic statements are true in virtue of their meaning.

Carnap's principle of tolerance was inspired by the debates concerning the foundations of mathematics in the 1920s. One party in this debate were the intuitionists, who did not believe that we have grounds to assert a mathematical sentence of the form 'p or \sim p,' unless we have a proof of either p or of \sim p. According to classical logic, the sentence 'p or \sim p' is a tautology; it therefore stands in no need of prior justification. Intuitionists, therefore needed to abandon classical logic in favor of a logic that would not count all instances of the law of the excluded middle (p or \sim p) as valid. Carnap saw both classical and intuitionistic logic as well motivated, and saw nothing that could decide between the two. He therefore saw the decision of which logic to adopt as a matter of choice.

Further developments in logic amplified the differences between Carnap and Wittgenstein. Gödel's famous incompleteness theorems made use of a technique that has since become known as Gödel numbering. By Gödel numbering we assign code numbers to expressions of the language. Through this coding technique, a language capable of expressing arithmetical properties becomes a device for discussing certain syntactic properties of any language system. Carnap saw this as a refutation of Wittgenstein's idea that the logical syntax of language is inexpressible. In fact, one of the general goals of Carnap's *The logical syntax of language* was to show that it is possible to deal in a clear systematic manner with the syntactic properties of any language. Recall that for Wittgenstein, we cannot say anything concerning the logical syntax of language.

Carnap's logical tolerance led him to assert that even statements of the form $(\exists x)Px$, which assert the existence of an object with the property P, might be true by stipulation. That we could stipulate an object into existence seemed odd to many philosophers.

In order to address this worry, Carnap formulated a distinction between *internal* and *external* questions of existence. In the language system of arithmetic it is provable that $(\exists x) (7 < x < 9)$. Relative to this language, the question of the existence of numbers is trivial. But when someone asks whether numbers exist they do not mean to be asking the questions in such a manner that it is answerable in by appeal to the standards of proof and disproof that prevail in arithmetic. Rather, they mean to ask if the numbers really exist in some absolute sense. Carnap viewed such 'external' questions as unanswerable given that they remove the questions from a context in which there are clear standards for addressing it, without embedding it in another context where there are any such standards. But the coherence of the language system that includes, for instance, the numbers does not depend on a positive answer to the external question of the existence of numbers. In this way, not only the logical structure of the world but its ontology as well becomes a matter of convention.

Quine: the Thesis of Gradualism

W. V. O. Quine (1908–2000) began his philosophical career as a self-described disciple of Carnap's. However, from his earliest interaction with Carnap, Quine questioned Carnap's strict division between analytic and synthetic sentences. This early reaction to Carnap's work grew into a major break between the two philosophers. Recall that the analytic/synthetic distinction divides sentences (respectively) into those that concern the world and are capable of being empirically confirmed, and those that are accepted by stipulation and are true in virtue of meaning. Quine thought that this difference in kind ought to be replaced with a difference of degree. This is known as the thesis of gradualism.

For Quine our knowledge forms a structure like a web. The nodes of the web are sentences and the links between nodes are entailment relations. Only at the periphery are our decisions to accept or reject sentences directly influenced by experience. Decisions over sentences closer to the center are of an increasingly 'theoretical' character, with accepted logical and mathematical statements forming the most central class. The ordering of sentences from periphery to interior is based on how willing we would be to abandon a sentence when revising our beliefs in light of new evidence. For sentences like 'this table is red' we can easily imagine a set of experiences that would lead us to abandon it. By contrast, it is far more difficult to imagine the experiences that would lead us to abandon ' $2 + 2 = 4$.' Abandoning this statement would entail a far more radical change in our

overall belief system. However, for Quine, the difference is one of degree, rather than kind. No sentence, mathematical, logical or otherwise, is ultimately immune from revision in light of experience. Physics, for instance, in departing from Euclidean geometry has abandoned sentences such as 'between any two points exactly one straight line can be drawn' once believed to be on the firmest foundation.

We have seen that, for Carnap, logico-mathematical truths are not responsible to any aspect of the world. We are perfectly free to accept any set of sentences to count as analytic. The way the world is affects only the practical utility of our choices of analytic statements; it does not affect the theoretical legitimacy of those choices. (However, Carnap is far more interested in giving reconstructions of existing notions instead of constructing arbitrary systems.) For Quine, on the other hand, logical and mathematical truths are on par with highly theoretical statements of physics. It may turn out that by abandoning classical logic or altering our mathematics we will be able to formulate more simple scientific theories. Since simplicity is one of the norms of theory choice, it may be that our best scientific theory does not conform to the laws of classical logic.

Carnap's principle of tolerance suggests that logical truths are true by virtue of the meanings assigned to the logical vocabulary. Quine rejects this view and sees logical truths as subject to the same standards of acceptance as any other scientific claim. Since there are a certain sets of experiences that would lead us to reject what we now regard as a logical truth, Quine maintained that we could no longer hold, as Wittgenstein did, that logical truths are true independently of how things happen to be in the empirical world. Logical truths therefore lose their special status and become statements on par with other scientific claims. They are true because they are part of our best description of the world.

Logical Consequence

P Blanchette, University of Notre Dame, Notre Dame, IN, USA

Fundamentals

Logical consequence is the relation that holds between the premises and conclusion of an argument when the conclusion *follows from* the premises, and does so for purely logical reasons. When a conclusion is a logical consequence of premises, the truth of those premises suffices to guarantee the truth of the conclusion. To clarify, we'll look at some examples.

When we reason that

(A1) Socrates is mortal

follows from

(A2) Socrates is human

and

(A3) All humans are mortal,

we need not appeal to any known facts about Socrates, about humanity, or about mortality. These specifics are irrelevant to the fact that (A1) follows from (A2) and (A3), which shows that the sense of 'following-from' involved here is the purely logical sense. That is, (A1) is a *logical* consequence of (A2) and (A3).

By contrast, when we reason that

(B1) There are mammals in the ocean

follows from

(B2) There are dolphins in the ocean

we must appeal to facts peculiar to the nature of mammals and of dolphins. We appeal, specifically, to the fact that dolphins are mammals. In this case, although there is a sense in which (B1) 'follows from' (B2), (B1) does not follow *logically* from (B2). It follows, one might say, *biologically*, because an appeal to biological facts is needed to get from (B2) to (B1). Nevertheless, the fact that (B1) follows in this extra-logical way from (B2) is because of the relation of logical consequence. Specifically, it is because of the fact that (B1) is a logical consequence of (B2) together with

(B3) All dolphins are mammals.

That (B1) is a *logical* consequence of (B2) and (B3) can be seen by noting that it follows from them independently of the specific nature of the objects, properties, and relations mentioned in these statements.

In general, all cases of 'following from' are due, in this way, to the relation of logical consequence. If a conclusion follows from some collection of premises, this is because that conclusion is a *logical* consequence of the premises, together perhaps with various ancillary claims that are presupposed in the given context.

Logical consequence is therefore a ubiquitous relation: all of our reasoning turns on recognizing (or attempting to recognize) relations of logical consequence, and virtually all of the important connections between theories, claims, predictions, and so on, are in large part due to logical consequence. Furthermore, whenever we say that a given argument is *valid* or that it is *invalid*, or that a particular set of claims is *consistent* or *inconsistent*, we are employing the notion of logical consequence: a valid argument is one the conclusion of which is a logical consequence of its premises, whereas a consistent set of claims is a collection that has no contradiction as a logical consequence. Because the central logical notions of validity, consistency, etc., are definable in terms of logical consequence, the investigation of the nature of logical consequence is at the same time the investigation of the nature of the logical properties and relations in general.

The Formal Study of Logical Consequence

The modern investigation of logical consequence is closely connected to the discipline of *formal logic*. Formal logic is the study of formal (i.e., syntactically specified) languages, and of various philosophically and mathematically significant properties and relations definable in terms of such languages. Of particular significance for the study of logical consequence are two kinds of relations definable on the formulas of a formal language, the relations of *proof-theoretic consequence* and of *model-theoretic consequence*.

Given a formal language, a relation of proof-theoretic consequence is defined via the rigid specification of those sequences of formulas that are to count as *proofs*. Typically, the specification is given by designating specific formulas as *axioms*, and designating some *rules of inference* by means of which formulas are provable one from another. Both axioms and rules of inference are specified entirely syntactically. A proof is then a series of formulas each of which is either taken as premise, or is an axiom, or is obtained by previous formulas in the series via a rule of inference. A formula φ is a proof-theoretic consequence of a set Σ of formulas if and only if there is a proof the premises of which are

among the members of Σ , and the conclusion of which is φ .

Model-theoretic consequence, by contrast, is defined in terms of a range of *interpretations* (or *models*) of the formal language in question. While the vocabulary of the language is divided into the 'logical' terms (typically, analogues of the English-language 'and,' 'or,' 'not,' 'if...then,' and 'for all'), the meaning of which is taken as unchanging, and the 'non-logical' terms (typically analogues of natural-language predicates and singular terms), an *interpretation* is an assignment of objects and sets of objects to the non-logical terms. In the standard case, the formulas are taken to have a truth-value (i.e., to be either true or false) on each such interpretation. A formula φ is then a model-theoretic consequence of a set Σ of formulas if and only if there is no interpretation on which each member of Σ is true while φ is false.

The connection between these defined relations and logical consequence arises when the formulas in question are taken to stand as representatives of natural-language sentences or the claims they express. Given such a representation-relationship, the relations of proof-theoretic and of model-theoretic consequence are typically designed so as to mirror, to some extent, the relation of logical consequence. Thus, the idea behind a standard design of a relation of proof-theoretic consequence is that it only count as axioms those formulas representing 'logical truths' (e.g., 'Either 5 is even or 5 is not even'), and that its rules of inference similarly mirror logical principles. In such a case, a formula φ will be a proof-theoretic consequence of a set Σ of formulas only if the kind of ordinary sentence represented by φ is indeed a logical consequence of the ordinary sentences represented by the members of Σ . This does not ensure that the relation of proof-theoretic consequence exhausts the relation of logical consequence, for two reasons: first of all, the formal language in question may not contain representatives of all ordinary sentences; second, the proof system may not be rich enough to reflect all of the instances of logical consequence amongst even those ordinary sentences that are represented in the language. The system of proof-theoretic consequence will, however, have the virtue of being well defined and tractable. Similar remarks apply to the relation of model-theoretic consequence: in a well-designed formal language, the relation of model-theoretic consequence will mirror, in important ways, the relation of logical consequence. The intention in designing such a system is, typically, that φ will be a model-theoretic consequence of Σ if and only if the kind of ordinary sentence represented by φ is a logical consequence of those represented by the members of Σ .

Given a particular language together with its proof-theoretic and model-theoretic consequence relations, the question arises whether those relations are co-extensive: whether, that is, φ is a proof-theoretic consequence of Σ if and only if φ is a model-theoretic consequence of Σ . In some cases, the answer is 'yes,' and, in some, 'no.' Each half of the inclusion is a separate, significant issue: when every proof-theoretic consequence of each set of formulas is also a model-theoretic consequence of that set, the system is said to be *sound*, and when every model-theoretic consequence of each set of formulas is also a proof-theoretic consequence of that set, the system is said to be *complete*. The soundness of a system is typically a straightforward matter, following immediately from the design of the proof-theoretic system; completeness is typically a considerably more significant issue. The most-important system of logic, that of classical first-order logic, was proven by Kurt Gödel in 1930 to be complete; this is the celebrated 'completeness theorem for first-order logic.' First-order logic is, in various ways, the 'strongest' complete system (see Enderton, 1972).

Formal systems, i.e., formal languages together with proof-theoretic or model-theoretic consequence relations, differ from each other in a number of ways. Most important for the purposes of the study of logical consequence are the following two differences: (1) proof-theoretic relations differ over the axioms and rules of inference they include, and hence over the instances of logical consequence that they represent. Some such differences are just because the languages of some such systems are expressively weaker than others, so that principles contained in one simply cannot be expressed in the other. More interesting are differences motivated by differing views of logical consequence itself. Thus, for example 'classical' logic differs from intuitionist logic in including the principle of *excluded middle*, the principle guaranteeing the truth of all statements of the form *p-or-not-p*. As the proponent of intuitionist logic sees it, this principle is not universally accurate, and hence should not be included in a system of logic. (2) Model-theoretic relations differ in a number of small ways, including the specifics of the definition of *interpretation*, and of the definition of truth-on-an-interpretation. More important, the model-theoretic consequence relations for different systems differ when the formal languages in question are importantly structurally different. Thus, for example, standard *second-order logic* has a richer model-theoretic consequence relation than does first-order logic, and there are natural-language arguments whose second-order representation yields a conclusion that is a

model-theoretic consequence of its premises, but whose first-order representation does not (see van Dalen, 2001; Shapiro, 1991).

The question of the extent to which each such system gives an accurate characterization of logical consequence is of central philosophical concern. With respect to the relations of proof-theoretic consequence, debate turns on the accuracy of specific axioms and rules of inference. With respect to relations of model-theoretic consequence, the significant debate is rather over the question of the extent to which model-theoretic consequence relations in general (or, perhaps, that relation as applied to classical first-order logic) offer an *analysis* of the ordinary, non-formal relation of logical consequence. If logical consequence is in some sense ‘essentially’ the relation of truth-preservation across interpretations, then model-theoretic consequence has a privileged position as simply a tidied-up version of the core relation of logical consequence. If, by contrast, the relation of truth-preservation across interpretations is simply another sometimes-accurate, sometimes-inaccurate means of representing the extension of the relation of logical consequence, then model-theoretic consequence has no immediate claim to accuracy (see Etchemendy, 1990).

General Philosophical Concerns

In addition to questions surrounding its appropriate formal representation, the investigation of logical consequence includes questions concerning the nature of the relation itself.

One important cluster of such questions concerns the relata of the relation. Here we want to know whether the items between which logical consequence holds are, say, the *sentences* of ordinary language, or the non-linguistic *propositions* expressed by such sentences, or something else altogether. Although logical consequence is perhaps most straightforwardly viewed as a relation between sentences, one reason to reject this idea is that sentences, at least when thought of as syntactic entities (strings of letters and spaces), seem the wrong kinds of things to bear that relation to one another. Because any given sentence so understood could, under different circumstances, have had a quite different meaning, and would thereby have borne different logical relationships to other sentences, it is arguable that the sentence itself is not the primary bearer of this relation but is, rather, just a means of expression of the primary bearer. This line of reasoning motivates the view of non-linguistic propositions, the kinds of things expressed by (utterances of) fully interpreted sentences, as the relata of

logical consequence. The central reason for rejecting *this* proposal, though, is skepticism about the existence of such things as nonlinguistic propositions. A third option is to take the relata of the logical consequence relation to be sentences-in-use, essentially pairs of sentences and meaning-conferring practices (see Cartwright, 1987; Strawson, 1957; Quine, 1970).

The second, related collection of questions concerning logical consequence arises from the inquiry into what *makes* one thing a logical consequence of others. Here, we are looking for an explanation or an analysis of logical consequence in terms of other, more well-understood notions. One potential answer is that logical consequence is to be explained in terms of the meanings of various specific parts of our vocabulary, specifically in terms of the meanings of the ‘logical’ words and phrases (see above). A second, not necessarily competing, account is that logical consequence is because of the *form*, or overall grammatical structure, of the sentences and arguments in question. A third type of answer, mentioned above, is that logical consequence is best explained in terms of model-theoretic consequence. Various of the accounts of logical consequence have been criticized on grounds of circularity: to say that φ ’s being a logical consequence of Σ is *because of* some other relation between φ and Σ is, arguably, to say that the claim that φ is a logical consequence of Σ is itself a *logical consequence* of the purported explanans. If this charge of circularity is accurate, it is arguable that all such explanations of the nature of logical consequence will be found to be circular, with the result that this relation must be taken to be ‘primitive,’ not capable of reduction to anything else. Part of the debate here will turn on what one takes the nature of explanation to be, and on whether explanation requires reduction (see Quine, 1936).

In short: although it generally is agreed that some claims are logical consequences of others, there is scope for important disagreement about (a) which specific claims are in fact logical consequences of which others, (b) how to construe the notion of ‘claim’ involved here, and (c) how to give a correct account of the nature of the relation of logical consequence. Because of the connections between these issues and general positions in the philosophy of logic, philosophy of mathematics, and philosophy of language, one’s preferred answers to the questions noted here will turn in large part on one’s position with respect to a host of surrounding topics.

Logical Form in Linguistics

D Blair, University of Western Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

To describe the logical form of some claim is to describe its logically significant properties and structure, showing its connection to other claims via what it entails and what it entails it. Given the variety of claims that philosophers have taken in an interest in, it is not surprising that there are a large number of theories of logical form. But even if there is no shortage of theories aiming at the logical form of, e.g., propositional attitude sentences or counterfactual conditionals, surprisingly little attention has been given to the prior question of **what** logical form is to begin with. Just as importantly, it is not clear what it is that is supposed to **have** a logical form in the first instance. Is it, for example, a linguistic object like a sentence, or the utterance of a sentence, or something different from both of these, such as the proposition expressed by an utterance of a sentence?

The presence of logic within the notion of logical form may make one suspicious of paying too much attention to the details of natural language. Other kinds of items seem better suited to having logical forms. For example, propositions have whatever truth conditions they have essentially, whereas sentences do not: 'snow is white' might have meant that most colorless beverages lack sodium. Further, it is a

notorious fact about natural language that it contains a good deal of vagueness and context sensitivity that is hard to capture within a theory of inference. Facts like these have made philosophers wary of placing too much emphasis on natural language sentences. At the very least, one would want to purge natural language of its logically problematic features before building upon it a theory of logical form. This was precisely the reaction of Frege (1952) and Russell (1919) to the defects of natural language. For them, one needed to formulate an ideal language free from the flaws of natural language in order to spell out the content of various claims. Only then could one think about constructing theories of logical form. Frege's *Begriffschrift* formulated an ideal language in which to conduct arithmetic and overcame some of the difficulties of explaining inferences involving multiple quantifiers that beset earlier logical theories.

But even if having a logically perspicuous representation of the propositional content of an assertion makes it easier to assess how well a theory accords with what is said about, e.g., the good or the propositional attitudes, there are serious questions concerning how such representations are related to the grammatical properties of a sentence. In the hands of Frege and Russell, one simply translated, as best one could, from natural language into an ideal language. These languages were specifically designed to expedite inference, and so no question arises about their logical forms.

But until the last few decades, the kinds of structures required for the purposes of detailing the inferential properties of natural language sentences were thought to be quite remote from anything one might call ‘the grammar’ of a language. Indeed, one way of **motivating** talk of logical form was by showing the deficiencies of theories of meaning built upon generalizations of apparent grammatical form and function.

A number of developments in the 1960s and 1970s changed this picture. A growing number of philosophers became intrigued with the idea of constructing theories of meaning for natural languages directly. The idea that such a theory could be done **systematically** stems in large part from the work of Noam Chomsky in the 1950s and 1960s, showing how rigorous theories of grammatical structure were possible. In light of the success of Chomsky’s program, it was natural to wonder whether a semantic theory along the lines of his work in syntax could be constructed. The classic picture of the grammatical structure of a sentence involves a series of levels of representation, the most well known of which is the so-called ‘T-model.’ In this model, there are four ‘levels of representation’: D-structure, S-structure, LF, and then PF, or the phonological form of a sentence. Since the last item is a representation of a sentence’s phonological properties, I leave it aside. Each level is related to the one before via the application of a rule or set of rules. The conception of rules has changed over the years, but the underlying idea is that syntactic structure of a sentence is built up, step by step, through a series of representations, each having its own properties. Diagrammatically, what we have is the following:

The ‘S-structure’ or surface structure of a sentence is what corresponds, nearly enough, to the order of expressions as heard or written. ‘LF’ or logical form is a syntactic representation that is derived from the S-structure via a set of transformations, just as S-structures were derived from D-structures via transformations.

Since only one level of representation seems to correspond to the overt form of a sentence, it follows that a good deal of syntactic structure remains hidden. The idea that unpronounced structure can

be given a grammatical motivation is compelling. Consider the following pair of sentences:

- (1) John kissed Mary
- (2) Who did John kiss

The leftmost WH-phrase in (2) is intuitively related to the position of ‘Mary’ in (1). The grammar of English disguises this fact by requiring that unstressed WH-phrases in sentences like (2) be fronted. Were English different in this regard, the parallel would be more obvious. Interestingly, a good many languages allow for just this possibility while others require all WH-phrases to be placed at the left- periphery of a sentence. A more perspicuous representation of English would abstract from these kinds of provincial eccentricities of surface form and expose, via a logically perspicuous notation, just these parallels.

There is evidence that the grammatical structure of sentences like these in different languages is abstractly identical, i.e., that all WH-phrases are located at the edge of a clause at some level of representation. In some languages, like Russian, this is overtly true, even when there are several WH phrases in the clause. In other cases, like Chinese, there is little or no movement to the edge of the clausal periphery (see Huang, 1982). The difference between the overt forms of WH-questions then doesn’t disguise just the logical or semantic structure of a sentence; it hides the grammatical structure as well. A more articulated version of (2) shows this abstract structure:

- (3) Who did John kiss *t*

The key idea is that movement of a WH-phrase may occur overtly, as in English, or ‘covertly,’ as in some cases of French. When the WH-phrase does move, however, what we end up with is (3) The movement of the WH-phrase to its position at the left edge of the clause leaves a record in the form of a ‘trace,’ notated above as ‘t.’

Structures like (3) resemble, in a rather striking way, the kinds of representations that one finds within first-order logic, in particular with respect to the relationship between a quantificational expression and a variable that it binds. Let’s look at this in more detail. It is now commonplace to use examples of scope ambiguities as evidence for the ambiguity of sentences, one to be sorted out in a semantic theory. Thus, a sentence like (4) is ambiguous depending upon whether or not one takes the quantificational phrase ‘every boy’ to have scope over the subject quantificational phrase ‘some girl’ or vice versa, i.e., (5a/b):

- (4) Some girl danced with every boy

- (5a) $\exists x: \text{girl}(x) [\forall y: \text{boy}(y) [\text{danced}(x,y)]]$
 (5b) $\forall y: \text{boy}(y) [\exists x: \text{girl}(x) [\text{danced}(x,y)]]$

The usual way of describing this difference is to say that in (5a), ‘some girl’ has scope over ‘every boy,’ while in (5b), the opposite relation holds. The scope of the quantifiers is determined by looking at the material appearing to its right, i.e., the closest formula that does not contain the expression within the first order translation.

It turns out that one can define the relevant relation in syntactic terms as well, using the properties of phrase structure. To see this, consider the core syntactic relation of c-command.

An expression α c-commands an expression β if and only if the first branching node dominating α dominates β and neither α nor β dominates the other.

What is important is that one can use this definition to say something about quantificational scope. Suppose we take quantificational expressions to move to positions from which they c-command their original position:

[ZP XP [ZP ... [... [... t_i ...]...]

In this case, XP c-commands ZP and everything that is contained in the latter, including the trace of XP. Strikingly, when we look at what the structure of 1 is when this structure is explicit, we see the kind of structure required for the definition of scope:

- (6) [_S [_{QP} Some girl]₂ [_S [_{QP} Every boy]₁
 [_S t_2 [_{VP} danced t_1]]]]

For the reading of (4) where the scopes of the quantificational NPs are inverted relative to their surface order, ‘every boy’ is adjoined to a position from which it c-commands both ZP and the position to which ‘some girl’ has been adjoined:

- (7) [_S [_{QP} Every boy]₁ [_S [_{QP} Some girl]₂ [_S t_2 [_{VP}
 danced t_1]]]]

Both of these movements can be given more detailed defense; see May (1977). The structures that seem to be needed for semantics and that philosophers have thought were disguised by ordinary grammar really are hidden, although not quite in the way they thought. What is hidden is more syntactic structure.

Of course, ‘LF’ is a *syntactic* level of representation and is not a semantic representation. This is not to suggest, however, that no gain has been made within theorizing about natural language by incorporating the LF hypothesis. For one could hold that the grammatical structures that are interpreted by the semantic

theory are just those provided by a theory of grammar incorporating the LF hypothesis. There is no need to first regiment the formal structures of sentences into something to which semantic rules could then apply. What one finds in the idea of LF is the idea that natural languages already have enough structure to supply a lot of what is needed for the purposes of semantics.

Further developments within syntactic theory have made the concept of logical form more prominent. Thus, Chomsky (1995) and others have proposed that the **only** level of grammatical representation is LF, although the role of LF is likely to change, just as it has in the past (see, e.g., Lasnik, 2001). Even so, it is apparent that progress has been made in joining together two bodies of thinking about language, one rooted in traditional philosophical problems about the representation of logic and inference and the other in more recent developments coming from linguistics.

There are limits, however, to how much philosophical work a linguistic-based approach to logical form can do. Recall that one of the problems that has made many philosophers wary of paying too much attention to natural language concerned such things as the context sensitivity of certain aspects of natural language sentences. It is an open question just how to treat different kinds of context sensitivity within natural language, and whether revisions are needed to our conception of logical form in natural language in order to accommodate it. It is also true that a good number of philosophical projects targeting logical form are usually concerned with the conceptual analysis of certain notions, e.g., moral goodness, knowledge, etc. Indeed, one of the traditional roles of logical form within philosophy is to serve as scaffolding for just these sorts of projects. Doubts about the viability of conceptual analysis to one side, this is what has given weight to the claim that ‘ordinary language’ disguises the logically significant structure of our concepts. But if this is the role that logical form must play if it is to have a role within philosophy, then it is unclear whether the linguistic conception of logical form can wholly supplant the traditional view. The linguistic conception of logical form seemingly has little to do with the conceptual analysis. And unless conceptual analysis takes the form of a grammatical analysis, it is unlikely that one can substitute grammatical analysis for the description of the logically significant aspects of our concepts.

This is not to deny that a linguistics-based conception of logical form is an important, maybe even essential part of understanding how to think about some aspects of logic and meaning. This is particularly clear with respect to the study of quantification. But there

are many questions about the nature of logical form that need to be resolved before particular view can be judged to be the most viable.

Lying, Honesty, and Promising

D Owens, University of Sheffield, Sheffield, UK

Promising and asserting are both speech acts, and as such they are regulated by practical norms as well as linguistic norms (e.g., norms of etiquette). Here we shall be concerned with the **moral** norms that govern these speech acts.

Informational Theories

Many philosophers take the view that the morality of an act – its rightness or wrongness – is a function of the harms and benefits this act brings to the agent and to others. These philosophers also hold that the main way promises and assertions affect the interests of human beings is when they serve as sources of information. So, they conclude, both promises and assertions are morally significant principally because, and in so far as, they purport to offer information. Let's call this the 'informational' view of the morality of promise and assertion. On this view, morality censures an unfulfilled promise or a false assertion because these deeds can harm others by giving them false information.

We are all obliged to take due care not to lead others to form false beliefs, at least where this might be harmful to them (Scanlon, 1998: 300). This obligation means that we must not set out to deceive people by making them insincere promises or telling them things that we know to be false. But it also means that we mustn't change our minds about what we promised we were going to do (without good reason) or make an assertion without adequate evidence. Someone who accepts a promise standardly forms the expectation that the promisor will perform, and they may rely on this expectation to their detriment. Someone who believes an assertion is similarly exposed, if this assertion turns out to be false. I'll deal with informational theories of promising first and then move onto assertion.

Information theorists of promissory obligation fall into two categories. First, there are those (sometimes called 'expectation theorists') who argue that we are all under an obligation not to mislead others about how we shall behave in the future and that this obligation is why we ought not to make them promises that we do not fulfill (Scanlon, 1998: Chap. 7; Thomson, 1990: Chap. 12). Second, there are those who argue that we are obliged to fulfill our promises only where there is an up and running practice of fulfilling

one's promises: prior to this, there is no promissory obligation. For such 'practice theorists,' promissory obligation is conventional (Hume, 1978: Book III, Part II, Section V; Anscombe, 1981; Prichard, 1968).

Practice theories differ from expectation theories in their account of how the obligation to keep a promise arises from our interest in having correct information about how other people are going to behave. According to the practice theorist, we can create expectations of performance in our audience by uttering words like "I promise" only where there is an actual practice of making such utterances true, i.e., where people have come to feel some obligation to make them true. So one can't explain the moral significance of this utterance simply by reference to the expectations it creates. Still the practice theorist agrees with the expectation theorist that we are obliged to maintain the practice of promise-making where it exists, because this practice serves our information interest and thereby aids the coordination of behavior.

Turning now to assertion, there is much controversy among philosophers of language about the extent to which language in general, and assertion in particular, involve social convention. For example, Davidson maintains that "there is no known, agreed upon, publicly recognizable convention for making assertions" (Davidson, 1984: 270), and he thinks the same is true of promising. On the other hand Fried urges that the promisor has "intentionally invoked a convention whose function it is to give grounds – moral grounds – for another to expect the promised performance" and "to abuse that confidence is like . . . lying: the abuse of a shared social institution that is intended to invoke the bonds of trust" (Fried, 1980: 16). Thus, there is a division among information theorists of the morality of assertion parallel to that between expectation and practice theorists of promissory obligation.

It has long been debated whether there is any morally significant difference between lying to someone and deceiving them in a more oblique fashion (e.g., by way of false implicatures, deliberate ambiguity, or by leaving misleading evidence around, etc.). And this debate reflects a genuine ambivalence in our everyday attitudes. Where we feel entitled to deceive others – for the sake of their health for instance – many of us are still inclined to go to the trouble of trying to avoid telling a direct lie. On the other hand, where such deception is wrong, the wrong is seldom thought to be mitigated just because a direct lie was avoided.

There is a tradition of thought, however, according to which lying is always wrong, but we are sometimes permitted to deceive in other ways (Aquinas, 1966: II-II 110 a3; MacIntyre, 1995: 309–318). But many contemporary writers have expressed doubts about

whether the manner of the deception could by itself make a serious moral difference (Sidgwick, 1981: 354–355; (Williams, 2002: 100–110). An expectation theorist who maintains that the wrong of lying is only the wrong of deception will share these doubts (Scanlon, 1998: 320). On the other hand, a practice theorist of the morality of assertion may allow that, in addition to any harm he does to the person he deceives, the liar is abusing and thereby undermining a valuable social practice (Kant, 1991: 612), namely the use of language to convey information.

Noninformational Theories

Until now, we have been assuming that what makes an act, including a speech act, wrong is, some harm that it does to those it wrongs in the end. There are many moral theorists who reject this assumption, and it is open to them to propound noninformational theories of what is wrong with a lie or a broken promise. Rather than attempt a comprehensive classification of noninformational theories, I shall consider one such theory of promising and one such theory of lying, both taken from Kant.

Take promising. Kant locates the moral significance of promising not in the information interests it serves but rather in the fact that it grants the promisee a certain moral authority over the promisor: it entitles the promisee to require the promisor to perform and thus deprives the promisor of a certain moral freedom (Kant, 1996: 57–61). If I promise you a lift home, I am obliged to give you a lift unless you release me from this promise. This line of thought was central to classical theories of promissory obligation (Hobbes, 1991: Chap. 2) and has found an echo in some contemporary writing (Hart, 1967: 60). For these authors, a breach of promise wrongs the promisee, whether or not it also harms them by inducing false expectations in them, because it flouts the moral authority that the promisee has acquired over the promisor.

On this view, informational theories miss what is distinctive about promising. There are many ways of influencing people's expectations and of co-ordinating your behavior with others (Raz, 1977: 215–216). For example, one can predict that one will do something or even express a sincere intention to do something, while making it clear that one is not promising. To promise to do it is to express the intention to undertake an obligation to do it (Searle, 1969: 60), an obligation that mere expressions of intention or predictions do not bring down on the speaker, however firm or confident they may be. If I predict, on excellent evidence, that I shall be going in your direction because the police will be towing my car in

that direction, I have not committed myself to making it true that I shall be going in your direction when that prediction threatens to be falsified.

Turning now to lying, Kant makes a firm distinction between wrong one does in deceiving someone and the wrong one does by lying (Kant, 1996: 182–184). One can lie without deceiving (e.g., when one knows one won't be believed) and one can deceive without lying. On deceiving someone you may wrong them but, according to Kant, when you lie, the person you wrong is yourself. The liar violates a duty to himself (though this violation need not involve harming himself). On explaining the nature of this wrong, Kant follows thinkers like Aquinas in attributing a natural teleology to speech:

communication of one's thoughts to someone through words that yet (intentionally) contain the contrary of what the speaker thinks on the subject is an end that is directly opposed to the natural purposiveness of the speaker's capacity to communicate his thoughts (Kant, 1996: 182).

In lying, one violates a duty to oneself by abusing one's own faculties, by using oneself "as a mere means (a speaking machine)" (Kant, 1996: 183). It may be possible to capture Kant's basic idea here without reference to natural teleology or duties to self if we adopt a certain view of assertion.

One can distinguish two currently influential theories of assertion. In the first, inspired by Grice, asserting that *p* is a matter of uttering something with the intention of thereby getting your audience to believe that *p*, by means of their recognition of that very intention (Grice, 1989). If something like this statement is correct, the moral significance of an utterance *qua* assertion must lie solely in the effect it is trying to achieve, i.e., in the effect that the assertion has on the beliefs of others. In the second view of assertion, asserting that *p* is more like promising that *p*. In promising, someone intentionally undertakes an obligation to perform: undertaking such obligations is what promising consists in. Similarly to assert a certain proposition is, on this view, to intentionally undertake an obligation to ensure that one asserts only what is true (Dummett, 1973: 299–302) and, perhaps, to defend one's assertions as true, should they be challenged (Brandom, 1983). Putting oneself under such obligations is what assertion consists of.

Once the second view is in play, we can say what is wrong about lying without making reference to the effect that the lie has on others. A liar is in the

wrong not because he is wronging someone but because he knows that he is taking on obligations he cannot discharge. In this way, lying differs from deception that wrongs the deceived when it harms their interests in some way. Deception is an offence against others while lying is an offence against truth. Provided morality is not solely concerned with harm, this offence may be counted as a moral wrong.

Mass Nouns, Count Nouns, and Non-count Nouns: Philosophical Aspects

H Laycock, Queen's University, Kingston, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Linguists often distinguish ‘count nouns’ (CNs) and ‘non-count nouns’ (NCNs) (designated as ‘count+’ and ‘count’ nouns, respectively). The distinction, though hardly simple, is both exhaustive and entirely natural. In philosophical writings, by contrast, it is more usual to posit a dichotomy of ‘count nouns’ and ‘mass nouns’ (MNs) – a dichotomy that is very commonly (and however vaguely) supposed to be of metaphysical or ontological significance. But this dichotomy, unlike that of CNs and NCNs, is deeply problematic; here, in consequence, I speak only of a **supposed** dichotomy of CNs and MNs, and by the same token, of a **putative** category of MNs.

Plural Count Nouns and Non-count Nouns

There is a certain kinship between NCNs and plural CNs, a kinship that has in recent years attracted some attention; see e.g., Schein (1994). What is less widely appreciated is the basis of this kinship in the actual semantic status of NCNs. Laycock (1998) urged that since CNs, or their occurrences, are semantically **either** singular or plural, to be non-count is simply to be **neither** singular nor plural. Non-count nouns are then semantically non-singular, and it is this that underlies their kinship with the plural (plural nouns themselves, it is evident, are non-singular). But being non-plural, the non-count form is never, unlike that of many plural sentences, reducible to the canonical singular form. The relationships between the semantics of CNs and NCNs may thus be simply represented in **Table 1** (Laycock, 1998). The inclusion of a contrast between ‘clothes’ and ‘clothing’ alongside that between ‘apples’ and ‘water’ serves to emphasize the point that the singular/non-singular contrasts in general (and not simply the singular/plural contrasts) are first and foremost **semantic** as opposed to **metaphysical** or **ontic**

contrasts (it being assumed that the ‘clothes’/‘clothing’ contrast itself is purely a semantic one).

Non-count nouns are to be classed as semantically non-singular, simply by virtue of being non-count. And given this, both quantification and denoting that involve such nouns also must be semantically non-singular. In the case of quantification, the non-singularity of NCNs is reflected in their obvious non-acceptance of singular quantifiers – in the fact that we may speak (as with plural nouns) of *all water*, *some water*, and *more water* but not in the singular of *a water*, *each water*, or *one water*. *Any*, *all*, and *some* interact with NCNs much as with essentially plural nouns; and *All n V made of polyester* and *The n in the warehouse V made of polyester* are related in essentially the same way, whether *n* is replaced by *clothes* and *V* by *are*, or *n* is replaced by *clothing* and *V* by *is*. The implications of the non-singularity of NCNs for the semantics of sentences containing definite descriptions and referential expressions are complex and extend beyond the remit of these brief remarks. However, the relatively common **mereological** interpretations of non-count reference take it to be semantically singular, designating individual ‘parcels of stuff’ or ‘quantities’ (see e.g., Bunt, 1985), and the non-singularity of NCNs is evidently not consistent with approaches of this type. Indeed, difficulties with the singularity assumption have been noted precisely in relation to Russell’s theory of singular descriptions, which maintains, as he puts it, that *the* “in the singular” involves **uniqueness** (Russell, 1956: 176); see e.g., Montague (1973) and Laycock (1975).

The Concept ‘Mass Noun’ and Its Supposed Criterion

Turning now to so-called MNs, perhaps the first use of an expression of the MN genre occurs in Jespersen (1924), who wrote of ‘mass words,’ contrasting these with what he called ‘countables’ or ‘thing words.’ And the thought that such words had a distinct metaphysical significance received the following expression in his work:

Table 1 Semantics of count nouns versus non-count nouns

	1. Singular (‘one’)	2. Non-singular (‘not-one’)
3. Plural (‘many’)	– – –	‘things’ ‘apples’ ‘clothes’
4. Non-plural (‘not-many’)	‘thing’ ‘apple’ ‘piece of clothing’	‘stuff’ ‘water’ ‘clothing’

There are a great many words which do not call up the idea of some definite thing with a certain shape or precise limits. I call these ‘mass-words’; they may be either material, in which case they denote some substance in itself independent of form, such as ... water, butter, gas, air, etc., or else immaterial, such as ... success, tact, commonsense, and ... satisfaction, admiration, refinement, from verbs, or ... restlessness, justice, safety, constancy, from adjectives. (Jespersen, 1924: 198)

Subsequent writers typically differ from Jespersen in treating the domain of ‘mass words’ as one of **concrete** nouns exclusively; but insofar as these latter nouns are concerned, Jespersen’s approach would seem to represent the norm. Thus if the question is raised, of what semantic element constitutes the putative MNs as a distinct category of concrete nouns, the answer tends to be that it is precisely some such element of ‘form-independence’ – an absence of ‘criteria of distinctness’ (Hacker, 1980) or of a ‘boundary-drawing,’ ‘individuating,’ ‘form-specifying,’ or ‘reference-dividing’ component in their meaning (Quine, 1960; Chappell, 1971; Talmy, 1978; Langacker, 1987; Jackendoff, 1991; Kleiber, 1997).

In this regard, Quine nicely represented the common view. To learn a “full-fledged general term” like ‘apple’ it is not enough, so he remarks, to learn “how much of what goes on counts as apple”: “we must learn how much counts as **an** apple, and how much as another. Such terms possess built-in modes ... of dividing their reference” (1960: 91). So-called ‘mass terms,’ in contrast, do not thus divide their reference. Water, Quine wrote, “is scattered in discrete pools and glassfuls... still it is just ‘pool,’ ‘glassful,’ and ‘object,’ not ‘water’... that divide their reference” (1960: 91). If such a noun is used to individuate a full-fledged, ‘substantial’ object, it needs an individuating adjunct. There is no learning “how much counts as **some** water and how much counts as **some more**”; there is no such distinction to learn. Whereas any sum of parts that are each an apple is not another apple, this lack of a boundary-drawing element confers upon the putative MNs what Quine called “the semantical property of referring cumulatively”: “any

sum of parts which are water is water,” as he puts it. I shall call this widely accepted criterion for distinguishing the putative category of MNs from CNs, in whichever of the various equivalent forms it is fleshed out, the ‘no built-in reference-division’ (no-RD) criterion. The key assumption that underlies the supposed dichotomy of CNs and MNs is, then, that possible borderline cases apart, there is a specific and more or less determinate category of concrete nouns that answers to the no-RD criterion – the putative category of MNs, to be precise.

Now, whereas the range of nouns that are categorized as MNs varies significantly from one writer to another, all the nouns that are thus categorized are in fact (and must be) NCNs. But here my concern is not with the nouns themselves; it is just with the putative **category**, as determined by the no-RD criterion, to which they are said to belong. And insofar as the use of the term ‘MN’ rests on this criterion, the contrast of CNs and MNs is quite fundamentally misconceived; the reality is that no such category as that of MNs exists. There are, on the contrary, two semantically distinct categories of nouns that answer to the no-RD criterion – concrete NCNs and concrete plural CNs (a fact that, given the common non-singularity of these two categories, is not altogether surprising).

An Illusory Criterion

Although the kinship of the putative MNs with concrete plural CNs is commonly remarked, it is less often noted that the no-RD criterion itself applies identically to the plural nouns. Thus, for instance, although we learn “how much counts as **an** apple, and how much as another,” there is no learning “how much counts as **some** apples, and how much as **more** apples” – there is no such distinction to learn. Although the singular *apple* applies to just one apple at a time, *apples* sets no limits on the count of apples. It is not the meaning content of the plural noun itself that sets whatever limits there may be; it is contingencies of context, including acts of demonstration – for example, *these apples* – that demarcate the subject matter of a discourse. *Apples* provides no criteria of distinctness or boundaries for what it collectively applies to – it does not, *qua* plural, carve what it applies to ‘at the joints.’ To play the role of designating full-fledged objects, each of which is apples, *apples*, much like *water*, needs an individuating adjunct (‘heap of _____,’ ‘bag of _____,’ or the like). Thus, if water may be characterized as ‘form-indifferent,’ then apples, too, collectively, may be so characterized. Much as the water in a glass might be spilled or dispersed and survive, so, too, might the apples in a bag. And so far as Quine’s ‘cumulative

reference' is concerned, whereas any sum of parts each of which is **an** apple will not be **another** apple, any sum of parts that are **apples** will simply be more **apples**.

The appearance of a dichotomy between CNs and the putative MNs then arises purely and simply because the chosen occurrences of CNs are **singular** exclusively – plural nouns are nowhere in the picture – and once plural occurrences of CNs are factored in, the supposed dichotomy with CNs disappears. Insofar as the no-RD criterion is conceived as definitional of the distinctive status of some putative 'metaphysically interesting' class of nouns, this putative category of nouns is ill-defined or ill-conceived, and talk of such a category is best abandoned. The only categories that are to be legitimately contrasted with CNs are those of NCNs as such and of the various subcategories of NCNs. And although metaphysically interesting distinctions between CNs and some sub-groups of NCNs certainly do exist, such distinctions have nothing to do with the spurious category of MNs. They are not, that is, a function of the no-RD criterion, obtaining as they do between various groups of nouns, **all of which** satisfy that criterion. (It is then hardly surprising that what is supposed to count as an MN varies significantly from one sponsor of the concept to another: the no-RD criterion does zero work, and it is rather individual metaphysical intuitions that actually determine whether a given NCN is to be assigned to the putative category or not.) What the no-RD criterion reflects is simply the contrast between CNs in the singular, and non-singular nouns altogether generally, whether NCNs or plural CNs. But the central contrast in this domain is rather one between distinct forms of non-singularity – the plural, and the non-count – and as such, to repeat, this contrast is purely a semantic one.

The point retains its relevance at the formal level of the contrast between 'stuff' and 'things' themselves. These words are formally NCNs and CNs, respectively; but whereas the contrast of stuff and things is not infrequently treated by sponsors of the 'MN' category as if it were a metaphysical distinction, the fact is that 'stuff' may be and is applied to **things** without restriction ('the stuff in the basement' may just denote a pile of pots and pans, garden tools, old chairs, and bicycles).

The Non-metaphysical Goods

We are left, then, with an essentially semantic contrast between concrete CNs and NCNs. And what this semantic contrast embodies are distinct modalities for the determination and specification of amount or quantity. Count nouns embody one such modality – trivially, that of counting through the use of natural

number-related words – *one horse, so many things, too few clothes, a dozen eggs, a single professor*, etc.; and in this intuitive sense, counting is applicable to the denotata of CNs **exclusively**. Non-count nouns, by contrast, involve a form of what is naturally called 'measurement': *so much cotton, too much stuff, so little water, five tons of clothing*, etc. And although the denotata of NCNs may be **only** measured and not also counted, measurement as such is applicable to the denotata of both NCNs and CNs alike. We may, for instance, speak both of *75 ccs of water* and *75 ccs of poppy seeds*, both of *5.5 kilos of clothing* and *5.5 kilos of apples*. Furthermore, it seems clear that in contrast with counting, **any** real number can in principle be assigned to the measure of an amount of something. The concept of weight, for instance, is such that it is intelligible to assign a weight of n kilos (where n represents an integer), or of $n \times \pi$ kilos, to a quantity of snow (or rice, apples, clothing, underwear, water, etc.).

Intuitively, then, counting may be described as the determination of 'discrete' or 'discontinuous' quantity and measuring the determination of 'continuous' quantity. Of the two, discrete quantity seems privileged: there is exactly one non-relative way of determining the quantity of, say, eggs in a carton, which is precisely to count them. But there is no such unique way of determining, say, the quantity of cotton in a warehouse; this might be done, e.g., by volume, or by weight, or indeed by counting the number of bales; and these different measures cannot be expected to be correlated in any uniquely determinate way.

The contrast of discrete and continuous quantity is not directly ontological – it is not a matter of whether something consists of discrete 'bits' (visible or otherwise) or not. We may count planets, eggs, or horses to determine their number; we may weigh apples, snow, or clothing to determine their amount. The non-ontic nature of the contrast is perhaps especially striking in the juxtaposition of such words as the CN *clothes* (or, e.g., *boots and shoes*) and its cognate collective NCN *clothing* (or *footwear*). Although *clothing* represents continuous quantity and *clothes* discrete quantity, to say that **there is** clothing here or there is to say no more than that **there are** clothes here or there. In this respect, there is good sense in the remark of Quine: "The contrast lies in the terms and not in the stuff they name ... 'shoe' ... and 'footwear' range over exactly the same scattered stuff" (1960: 91).

The contrast 'lies in the terms': although there are **units** of clothing, furniture, etc. (individual pieces of clothing, pieces of furniture, etc.) – indeed, while collective nouns like *clothing* and *furniture* might be said to be ontologically **equivalent** to cognate CNs – such NCNs are no less **semantically** non-count than

non-collective nouns like *water* and *mashed potato*. Thus, although there is a straightforward sense to talk of the smallest **number** of clothes – a single item of clothing – there is no good sense to talk of the smallest **amount** of clothing – is one woolen winter coat the same amount of clothing as a single nylon stocking? In absolute terms, I've suggested, talk of amounts in relation to the denotata of NCNs (collective or otherwise) is simply ill-defined; and relative to some particular dimension such as weight or volume, there is no semantic rationale for specifying minimum amounts.

But although not directly ontological, the contrast of discrete and continuous quantity involves the **possibility** of certain ontic contrasts. Counting truisitically involves discrete units; and although what is measured may consist of discrete units, measurement as such does not require it, and there are ontic category-differences **within** the semantic category of NCNs. Thus, contrast the two groups of NCNs (a) *furniture, footwear, and clothing*, and (b) *rubble, sand, and snow*, with what may be called the 'pure' NCNs of group (c): *mashed potato, wine, and water*. The collective nouns of group (a) may be said to be 'object-involving,' in that they are semantically 'atomic' – there are units of furniture, footwear, and clothing that are not divisible into smaller units of furniture, footwear, and clothing. It is part of the **meaning** of such an NCN that like a typical CN, it ranges over discrete pieces, units, or elements of what the NCN denotes; indeed the very **identity** of some furniture is not to be distinguished from that of some pieces of furniture. For this reason, the identity of the denotata of group (a) nouns is independent of the identity of the materials of which those denotata are composed; some furniture can survive some loss of constituent materials – wood, cloth, stuffing, etc. – and remain the same (arguably, indeed, it is conceivable that all of the materials of some furniture could be replaced over time while the furniture retains its identity). But the same can hardly be said of the nouns in groups (b) and (c).

Now group (b), though not thus atomic, are object-involving in that they may be said to be 'semantically particulate': it is part of their meaning that what these words denote consists of discrete grains, flakes, bits, etc. – the difference being that the identity of some sand (snow, rubble, etc.) is **not** dependent on that of certain particular grains, flakes, or bits; it may be further crushed or pulverized and yet remain the same. In contrast with groups (a) and (b), however, no such object-involving concepts enter into the meanings of the group (c) terms. Whereas, for instance, to say that there is furniture or clothing in some region is to say that there are constituent pieces or units of furniture or clothing in that region, to say that there

is wine or mashed potato in some region is not to say that there are objects that can be characterized as 'pieces' or 'units' of wine or mashed potato in that region. In the nature of the case, there is here no comparable notion of a constituent piece or unit.

Maxims and Flouting

A K Greenall, Norwegian University of Science and Technology, Trondheim, Norway

© 2006 Elsevier Ltd. All rights reserved.

Maxims and *flouting* are two closely interrelated terms central to the Oxford language philosopher H. Paul Grice's famous theory of the Cooperative Principle, which first emerged in the William James lectures that Grice delivered at Harvard University in 1967 (see **Cooperative Principle**). Grice's project was to try to reduce the number of meanings for lexical items ("Grice's razor" [Davis, 1998: 20]), and he did this by postulating a new, separate type of non-semantic meaning that he called *implicature*, a type of meaning that is not semantically coded but arises in conversational context (see **Implicature**).

The generation of implicature is crucially connected to the workings of an overall *Cooperative Principle* and a set of conversational *maxims*.

The Cooperative Principle

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged (Grice, 1989).

The Maxims

Quantity

1. Make your contribution as informative as is required.
2. Do not make your contribution more informative than is required.

Quality

1. Do not say what you believe to be false.
2. Do not say that for which you lack adequate evidence.

Relation

1. Be relevant.

Manner

1. Avoid obscurity of expression.
2. Avoid ambiguity.
3. Be brief.
4. Be orderly.

These maxims may either be observed or breached, and in both cases implicatures may arise. The maxims can be contravened in a number of different ways, but crucial importance was allotted to the *blatant*, *intentional* contravention of one (or more of the) maxim(s), or *flouting*. On spotting such a blatant breach, the hearer – who will always retain his or her belief that the speaker is being cooperative – will immediately begin a search for an additional or alternative meaning for the utterance, one that *observes* the maxim(s) in question and thus follows the Cooperative Principle. The result of such a search is the implicature. Consider the following example:

- A: Are you going to Anna's party?
B: Well, Anna's got this new boyfriend now.

B's reply here clearly breaches Grice's maxim of Relation (the only truly relevant answers to A's question would be *yes* or *no*). According to the theory, spotting this breach would set off a reasoning process in A, along the following lines:

1. B has said that *Anna's got this new boyfriend now*.
2. This utterance breaches the maxim of Relation.
3. I have, nevertheless, no reason to believe that B does not intend to observe the Cooperative Principle and the maxims.
4. B could not be doing this unless what he really wanted to convey was something different from what he literally says.

5. On the basis of the available context (e.g., that B really liked Anna's old boyfriend), what B really wanted to convey was, *no* (*I am not going to Anna's party*) (a *relevant* reply, i.e., one that is not in breach of the maxim of Relation).

Note how this example illustrates the context-dependency of implicatures. If the context assumed in 5 were *B really disliked Anna's old boyfriend*, the interpretation (implicature) would be the opposite, namely, *yes* (*I am going to Anna's party*).

What Is a Maxim?

The concept of maxim is a crucial notion within the theory of the Cooperative Principle. Grice's own characterization of the entity is many-faceted. First of all, he was unambiguous on the point that the maxims are descriptive rather than prescriptive. Our rational nature, according to Grice, leads to the observable situation that the maxims are observed (more often than not). That is, he never meant that the maxims *should always* be observed, one of several common misunderstandings which has marred the field of Gricean pragmatics since its beginning (Thomas, 1995: 56).

Another noteworthy aspect of Grice's characterization of his maxims is that just because they are seen to have a basis in human rationality, they are not therefore to be considered innate. Furthermore, he was also attracted to the idea of maxims as *general interactional principles* governing both non-verbal and verbal behavior. Finally, the proposed set of maxims was seen as *expandable*: "There are, of course, all sorts of other maxims (aesthetic, social, or moral in character), such as 'Be polite,' that are also normally observed by participants in talk exchanges, and these may also generate . . . implicatures" (Grice, 1989: 28).

In the post-Gricean literature, there are roughly three main approaches to maxims. The first tries to tighten the association between the maxims and human rationality. The main representative of this approach, Asa Kasher, does this by postulating principles of rationality from which Grice's maxims are seen to derive (Kasher, 1976). The second, more influential approach, alienates itself most strongly from Grice's original formulation: here, the maxims are redefined as innate, linguistic rules that are always observed and that will produce the same implicatures irrespective of context (e.g., Atlas and Levinson, 1981; Horn, 1984). This formalist, cognitivist approach, in its quest to 'purge' the Gricean scheme, often ends up reducing the number of proposed maxims, a trend that culminated in the theory of relevance proposed by Sperber and Wilson in 1986, in which all the maxims were collapsed into one, cognitive,

Principle of Relevance. This is in stark contrast to a completely opposite trend, found in the third approach to maxims, the social pragmatics approach. Geoffrey Leech (1983), adopting Grice's view of maxims as learned entities, ends up adding a large number of maxims to Grice's scheme.

The main drawback of the formalist, cognitivist approach is clear: they see maxims as rules that are in principle always followed, and hence this kind of theory cannot account for that which is observed when some such entity as a maxim is *breached* (e.g., flouted), namely, the emergence of a layer of underlying meaning (implicature). Support for this observation has come from a perhaps unusual angle: research in Artificial Intelligence has shown that, in order for computers to communicate efficiently with human beings, they need to observe all the Gricean maxims at all times. If they do not, the human communicator will invariably read more into the computer's utterance than the devisers of the program intended (Bernsen *et al.*, 1996).

The main criticism of the social pragmatic approach has revolved around their uncritical, *ad hoc* proliferation of maxims (see, e.g., Brown and Levinson, 1987). A weakness of *all* approaches, including the social pragmatics approach, is the widespread belief that there must be an ultimate, fixed set of universal maxims where each can be classified and labeled individually. This despite the fact that the universality of maxims was drawn strongly into question as early as the mid-1970s, in Elinor Keenan's (1976) famous study of a Malagasy community, in which the influence of an informativity maxim (Quantity) was shown to be absent in certain speech situations. Unfortunately, rather than drawing attention to the eclectic sociocultural reality of Gricean maxims and other such entities, Keenan's work was applauded as a refutation of Grice's claims by those who believe that universality is the only valid stamp of approval for maxims.

The varied appearance of maxims around the world makes likely the hypothesis that one cannot ever hope to be able to enumerate and label every single maxim – the list of entities that can be flouted to produce implicature is probably open-ended. This, of course, calls for a detailed and succinct definition of the notion, to stand guard at the door, controlling which new maxims get in. A simple solution would be to adopt a functional definition such as that proposed by François Recanati (1987: 133), to the effect that a maxim is an entity that can be flouted to produce implicature (see also Levinson's 'general principle' [1983: 132]). The success of such a definition would, however, depend on whether or not one has reached a satisfactory understanding of the notion of *flouting*.

Flouting: Past, Present, and Future

As was noted in the first section of this article, flouting is the blatant breach of one of the maxims. Because all hearers embody faith in the speaker's inherent intention to be cooperative (i.e., to observe the maxims [at some level]), a seeming breach will trigger a reasoning process whereby the hearer will try to come up with a meaning for the utterance that *turns it into* an act of observing the given maxim(s) (an implicature).

There are several problems with this model. First of all, it is unlikely that it is the hearer's belief in the speaker's cooperativity that is the reason behind the former's quest to retrieve an implicature. This is especially the case if one chooses to include politeness maxims into the scheme: if a politeness maxim is breached, the implicature is hardly ever more polite than the act itself (consider, e.g., the act of turning away when one should have greeted somebody, in order to implicate, for instance, that one considers that person to have done something despicable). Another serious problem is that the reasoning process the hearer is supposed to go through is psychologically implausible. And finally, the end product of this process, the implicature, is presented as an entity that is easily circumscribed (a fully fledged proposition), whereas real life might prove to be far less ordered, with several half-formed, semi-verbalized hypotheses as outcome.

Despite these problems, which are clearly in need of serious attention, there has been a curious neglect of the notion of flouting in post-Gricean theory-building. The interest from empirical researchers has, by contrast, been tremendous. The notion is used as an analytical tool in a large array of studies in a multitude of extra-pragmatic and semi-pragmatic fields such as, e.g., literary criticism (e.g., Bollobás, 1981), humor studies (e.g., Attardo, 1990), or gender studies (Rundquist, 1992). Such widespread application clearly confirms the theoretical value of the notion. However, as very few have felt the need to make any significant amendments to the theory (apart from the occasional addition of a 'new maxim'), the problems remain.

In the theoretical literature, it is mainly the strong focus on observance (largely because of a reluctance to deal with the troublesome notion of context) that has obscured the need to deal with the notion of flouting. The discussion above related the formalist approach with their definition of maxims as context-independent rules that are always to be observed. Another trend manifests itself by interpreting every observed breach of a maxim not as a breach, but as the observance of an invented, 'opposite' maxim

(e.g., a breach of Be brief would be seen as an observation of 'Be wordy') (see, e.g., Joshi, 1982).

A particularly serious form of neglect is, of course, outright rejection, as in Sperber and Wilson's highly influential, and heavily criticized, Relevance Theory (1995). (see **Relevance Theory**.) Maxims, as envisaged by Grice, are afforded no place in a theory of indirectness, and the notion of flouting leading to implicature is replaced by the idea that implicature should be arrived at by a continued search for relevance, when the literal interpretation yields none. The problem for Relevance Theory is, of course, empirical evidence such as that mentioned in the previous section (Bernsen *et al.*, 1996), which shows without a shadow of a doubt that maxims (or something like them) *are* involved and that breaching them *does* have the effect of stimulating the interpretation of indirect meaning. In addition, there are interesting indications that Grice may have stumbled on to something that is in reality part of an even larger scheme than he envisaged. In experimental social psychology, it has long been noted that 'unusual events' are sociocognitive triggers for a search for an 'explanation' (the 'expectancy principle' [Weiner, 1985: 81]). The breach of a maxim, being the departure from a norm, is also in this sense an 'unusual event,' and the search for an implicature has much in common with the description of the search for an 'explanation.' If this connection is viable, it holds great promise for the further development of Grice's model of flouting.

Conclusion

All in all, Grice himself offered merely 20 or so pages on the topic of maxims and flouting. Subsequent research offers much food for thought, but no viable theory has emerged that exploits the full potential of Grice's eminent point of departure. This does not mean that it is an impossible task to arrive at such a theory, but it would probably require a considerable reorientation of focus, possibly toward the sociocultural significance of both maxims and flouting.

Meaning: Cognitive Dependency of Lexical Meaning

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

It is often thought or implicitly assumed, even in circles of professional semanticists, that predicate meanings, as codified in their satisfaction conditions, are lexically fixed in such a way that they automatically produce truth or falsity when applied to appropriate reference objects. This assumption is unfounded. In many, perhaps most, cases, the satisfaction conditions imply an appeal to nonlinguistic knowledge, so that the truth and falsity of assertive utterances are not the product of mere linguistic compositional computation, but are codetermined by nonlinguistic knowledge, either of a general encyclopedic or of a context-bound, situational nature.

An obvious case is provided by a large class of gradable adjectival predicates, such as *expensive*, *old*, and *large*, whose applicability depends on (preferably socially recognized) standards of cost, age, and size, respectively, for the objects denoted by their subject terms. The description of such standards is not part of the description of the language concerned, but of (socially shared) knowledge.

Further obvious examples are 'possession' predicates, such as English *have*, *lack*, and *with(out)*, and whatever lexical specification is needed for genitives,

datives, and possessive pronouns. These clearly require general encyclopedic knowledge for their proper interpretation. Consider the following examples:

- (1a) This hotel room has a bathroom.
- (1b) This student has a supervisor.

For (1a) to be true, it is necessary that there be one unique bathroom directly connected with the room in question, whose use is reserved for the occupants of that room. When the room carries a notice that its bathroom is at the end of the corridor to the right, while the same bathroom serves all the other rooms in the corridor, (1a) is false – not just misleading but false, as any judge presiding over a court case brought by a dissatisfied customer will agree. But for (1b) to be true, no such uniqueness relation is required, as one supervisor may have many students to look after. This is not a question of knowing English, but of knowing about the world as it happens to be.

The same goes for the parallel sentences:

- (2a) This is a hotel room with a bathroom.
- (2b) This is a student with a supervisor.

Possession predicates, therefore, must be specified in the lexicon as involving an appeal to what is normally the case regarding their term referents. They express a well-known relation of appurtenance between the kind of object referred to in subject position and the kind of object referred to in object position.

The semantic description (satisfaction conditions) of *have* and other possessive predicates is thus taken to contain a parameter for 'what is well-known,' making the interpretation of this predicate in each token occurrence truth-conditionally dependent on world knowledge.

Not all possession predicates are subject to the same conditions. Possessive pronouns, for example, may express a relation of 'being responsible for' or 'taking care of,' which other possession predicates cannot express. An example is sentence (3) uttered by a gardener with regard to the flower beds he is tending:

(3) Please don't mess up my flower beds.

This sentence can be uttered appropriately without the speaker implying that the flower beds are owned by him.

Many such examples can be given. Consider the predicate *flat* said of a road, a tire, a mountain, a face, or the world. There is an overall element 'spread out, preferably horizontally, without too much in the way of protrusions or elevations,' but that in itself is insufficient to determine what 'being flat' amounts to in these cases. The full meaning comes across only if it is known what roads, tires, mountains, faces, and the world are normally thought to be like. Dictionaries, even the best ones, limit themselves to giving examples, hoping that the user will get the hint.

Another example is the predicate *fond of*, as in:

(4a) John is fond of his dog.

(4b) John is fond of cherries.

(4c) John is fond of mice.

In (4a), obviously, John's fondness is of a rather different nature from what is found in (4b): the fondness expressed in the one is clearly incompatible with the fondness expressed in the other. The fondness of (4c) can be either of the kind expressed in (4a) or of the kind expressed in (4b). The common element in the status assigned to the object-term referents is something like 'being the object of one's affection or of one's pleasure,' but again, such a condition is insufficient to determine full interpretation.

Cognitive dependency is an essential aspect in the description of predicate meanings. The fact that some predicate meanings contain a parameter referring to an available nonlinguistic but language-independent, cognitive knowledge base means that neither utterance-token interpretation nor sentence-type meaning is compositional in the accepted sense of being derivable by (model-theoretic) computation from the linguistic elements alone. As regards utterance-token interpretation, this is already widely accepted, owing to valuable work done in

pragmatics. The noncompositionality of sentence-type meaning, defined at the level of language description, is likewise beginning to be accepted by theorists of natural language. This type-level noncompositionality does not mean, however, that the specification of the satisfaction conditions of predicates is not truth-conditional, only that standards embodied in socially accepted knowledge have become part of the truth conditions of sentences in which the predicate occurs.

In most treatises on lexicology, the term polysemy is used for phenomena such as those presented above. At the same time, however, it is widely recognized that this is, in fact, little more than a term used to give the problem a name. The problem itself lies in the psychology of concepts. One may assume that there are socially shared concepts like 'possession,' 'flatness,' and 'fondness,' but it is not known in what terms such concepts are to be defined. In a general sense, Fodor (1975, 1998) is probably right in insisting that lexical meanings are direct reflexes of concepts that have their abode in cognition but outside language. The necessary and sufficient conditions taken to define the corresponding lexical meanings cannot, according to Fodor, be formulated in natural language terms, but must be formulated in a 'language of thought,' which is categorically different from any natural language and whose terms and combinatorial properties will have to be established as a result of psychological theorizing.

It is clear, in any case, that phenomena like those shown in (1)–(4) pose a serious threat to any attempt at setting up a model-theoretic theory of lexical meaning, such as Dowty (1979): the neglect of the cognitive factor quickly becomes fatal in lexical semantics.

Context-bound or situational knowledge plays a role in the interpretation of predicates that involve a 'view-point' or 'perspective,' such as the pair *come* and *go*, or predicates such as *to the right (left) of*, *in front of*, and *behind*. The two versions of (5) are truth-conditionally identical, but they differ semantically in that the 'mental camera,' so to speak, has stayed in the corridor in the *went* version, but has moved along with Dick into the office in the *came* version.

(5) Dick and Harry were waiting in the corridor.

Then Dick was called into the office. After five minutes, Harry [went/came] in too.

In similar manner, the sentences (6a) and (6b) may describe the same situation, but from different points of view. In (6a), schematically speaking, the viewer, the tree, and the statue are in a straight line; in (6b), it is the viewer, the tree, and the fountain that are in a straight line:

- (6a) There was a statue behind the tree, and a fountain to the left of the tree.
- (6b) There was a fountain behind the tree, and a statue to the right of the tree.

A further cognitive criterion for the lexical meaning of predicates, especially those denoting artifacts, seems to be the function of the objects denoted. What defines a table or a chair is not their physical shape or the material they are made of, but their socially recognized function. The same holds for a concept like 'luxury.' Laws imposing special taxation on luxury goods or luxury activities usually enumerate the goods and activities in question, making exceptions for special cases (such as frock coats for undertakers). Yet what defines luxury is not a list of goods or activities, but socially recognized function – roughly, anything relatively expensive and exceeding the necessities of life.

A peculiar example of cognitive dependency, probably based on function, is provided by the English noun *threshold* and its Standard German translation equivalent *Schwelle*. In their normal uses, they denote the ridge or sill usually found between doorposts at floor level. Yet these two words differ in their capacity for semantic extension: the elevations in roads and streets that are normally called *speed bumps* in English are called *Schwelle* in German. Yet it is

unthinkable that speed bumps should be called *thresholds* in English. The question is: why? One is inclined to think that, at some ill-understood level of interpretation, the word *threshold* implies containment within a space or a transition from one kind of space to another, perhaps as a result of its etymology (which is not fully known). *Schwelle*, by contrast, is a swelling in the ground that forms an obstacle to be got over – which is also its etymology, although, on the whole, German speakers do not realize that. The difference between the two words is not a question of the ontological properties of the objects concerned, but, apparently, of the ways they are conceived of. The role of etymology in this case is intriguing.

Meaning: Development

E V Clark, Stanford University, Stanford, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

How do children assign meanings to words? This task is central to the acquisition of a language: words allow for the expression of the speaker's intentions, they combine to form larger constructions, and the conventional meanings they have license their use for making references in context. Without them, there is no language. In the acquisition of meaning, children must solve the general mapping problem of how to line up word forms with word meanings. The forms are the words they hear from other (mainly adult) speakers. The meanings they must discern in part from consistencies in speaker usage in context from one occasion to the next and in part from inferences licensed by the speaker on each occasion. Possible meanings for unfamiliar words, then, are built up partly from children's conceptual representations of events and partly from the social interactions at the heart of adult-child conversation.

One critical task for children is that of working out the conventional meanings of individual words (e.g., *cup*, *team*, *friend*, *truth*). Yet, doing so is not enough: syntactic constructions also carry meanings that combine with the meanings contributed by the actual words used (causative constructions, as in *They broke the cup* or *The boy made the pony jump*; the locative construction, as in *She put the carving on the shelf*; the resultative construction, as in *He washed the floor clean*). However, children start mapping word meanings before they begin combining words.

Languages differ in how they lexicalize information – how they combine particular elements of meaning into words – and in the kinds of grammatical information that have to be expressed. They may package information about events differently; for example, combining motion and direction in a single word (*depart*) or not (*go + toward*), combining motion and manner (*stroll*), or not (*walk slowly*). They also differ in the grammatical distinctions made in each utterance. Some always indicate

whether an activity was completed; others leave that to be inferred. Some always indicate whether the speaker is reporting from direct observation, or, for example, from the report of someone else. Some indicate whether object-properties are inherent or temporary. The grammatical distinctions that languages draw on vary, as do the ways in which they lexicalize information about objects and events. Mapping meanings onto words is not simply a matter of equating meanings with conceptual categories. Children have to select and organize conceptual information as they work out what the conventional meanings are for the words they are learning.

How do children arrive at the meanings they first assign to unfamiliar words? How do they identify their intended referents? And how do they arrive at the relations that link word meanings in different ways? The general conversational context itself serves to identify relevant information on each occasion for children trying to work out the meaning of an unfamiliar word. Adult language use presents them with critical information about how words are used, their conventional meanings, and the connections among words in particular domains.

Conventionality and Contrast

Adult speakers observe two general pragmatic principles when they converse. First, they adhere to the conventions of the language they are speaking and in so doing make sure their addressees identify the meanings intended in their utterances. The principle of conventionality takes the following form: 'For certain meanings, there is a form that speakers expect to be used in the language community.' So if there is a conventional term that means what the speaker wishes to convey, that is the term to use. If the speaker fails to use it or uses it in an unusual way, that speaker risks being misunderstood. For conventions to be effective, conventional meanings must be given priority over any nonconventional ones. The second general principle speakers observe is that of contrast: 'Speakers take every difference in form to mark a difference in meaning.' When speakers choose a word, they do so for a reason, so any change in word choice means they are expressing a different meaning.

These two principles work hand-in-hand with the Cooperative principle in conversation and its attendant maxims of quality (be truthful), quantity (be as informative as required), relation (make your contribution relevant), and manner (avoid ambiguity; Grice, 1989). Acting in a cooperative manner demands that one observe the conventions of the language in order to be understood. At the same time, if there is no conventional term available for the meaning to be

expressed, speakers can coin one, provided they do so in such a way that the addressee will be able to interpret the coinage as intended (Clark, 1993).

In Conversation

Adults talk to young children from the very start, and what they say is usually tied closely to specific objects and activities. This feature of conversation presents young infants with opportunities to discern different intentions, marked by different utterances from early on. Infants attend to adult intentions and goals as early as 12 months of age. They show this, for example, by tracking adult gaze and adult pointing toward objects (e.g., Carpenter *et al.*, 1998), so if they are also attentive to the routine words and phrases used on each type of occasion, they have a starting point for discerning rational choices among contrasting terms and gestures.

Consider the general conditions for conversational exchange: joint attention, physical co-presence, and conversational co-presence. Adults observe these conditions and indeed impose them, as they talk to very young children. They work to get 1- and 2-year-olds to attend, for instance when planning to tell them about an unfamiliar object, and only then do they talk to them about whatever object or event is visibly present (Clark, 2001). By first establishing joint attention, adults set young children up to identify and then to help add to common ground. Children can do this by ratifying offers of new words by repeating them or else indicating in some other way that they have taken up an unfamiliar term (Clark, 2003).

When adults offer unfamiliar words, they do so in the conversational context; that is, with children who are already attending to whatever is in the locus of joint attention. This feature, along with any familiar terms that are co-present in the conversation, allows children to make a preliminary mapping by identifying the intended referent, whether it is an object or an action (Tomasello, 2002). In effect, the conditions on conversation narrow down the possible meanings that young children might consider for a new term to whatever is in the current joint focus of attention.

However, adults do more in conversation. They accompany their offers of unfamiliar words with additional information about the intended referent on that occasion and about how the target word is related to other terms in the same semantic field. Among the semantic relations adults commonly offer are inclusion (*An X is a kind of Y*), meronymy or partonymy (*An X is part of Y*), possession (*X belongs to Y*), and function (*X is used for Y*; Clark and Wong, 2002). After offering one term, adults often offer others that happen to contrast in

that context, so a dimensional term like *tall* may be followed up by *short*, *wide*, *narrow*, and *long* (Rogers, 1978). In fact, the meanings of words for unfamiliar actions may also be inferred in part from their co-occurrence with terms for familiar objects affected by those actions, and the meanings of words for unfamiliar objects may be inferred in part from the verbs with which the nouns in question occur (e.g., Goodman *et al.*, 1998; Bowerman, 2005). All this information offers ways for children to link new terms to any relevant words they already know. Children learn from child-directed speech about general properties of the lexicon – taxonomic relations, nonoverlapping categories within levels, opposites, overlaps in meaning (through hierarchical connections) vs. in reference, and so on.

In short, adults are the experts in providing the conventional terms used for specific meanings in the speech community. The novices, children, ask them innumerable *What's that?* questions from around age 2;0–2;6 on and treat them as reliable sources for how to talk about new things (e.g., Diesendruck and Markson, 2001). Moreover, when young children make errors, adults frequently check up, through side sequences and embedded corrections, on what they intended to say, and so present children with the conventional forms to aim for (Chouinard and Clark, 2003).

Making Inferences

When children hear a new term for some object or activity, they can infer in context that the term probably applies to the object or activity to which they are attending. However, the information that adults often follow up with allows children to make more detailed inferences about the candidate meaning. Mention of class membership – for example, *A sparrow is a bird* – tells them that they can add the term *sparrow* to the set of terms they already know for birds, perhaps just *chicken* and *duck*. Comments on the size, characteristic song, or flight each allow further inferences about how sparrows differ from ducks and chickens.

What evidence is there that young children take in such information? In spontaneous conversations, they give evidence of attending to what adults say in several ways. First, they repeat new terms in their next conversational turn, either as single words or embedded in a larger utterance; second, they acknowledge the adult offer with forms like *yeah*, *uh-huh*, and *mmh*; and third, they continue to talk about the relevant semantic domain (Clark, 2004).

Children's readiness to make inferences from added information offered by adults has also been examined

in word-learning experiments. In one study, children aged just 2 years old were taught words for two sets of objects (A and B) that were similar in appearance and had the same function. After teaching the first word for the first set (A), the experimenter introduced the second set of objects while saying just once, "Bs are a kind of A." He then proceeded to teach the second word, B. Children were then tested by asking them to find all the As and then all the Bs. For the first request, they typically selected As; for the second, they consistently (and correctly) picked only Bs (Clark and Grossman, 1998). In short, the one statement of an inclusion relation was enough for even young 2-year-olds to make use of it in this task. In another condition, again teaching two new words for two sets that resembled each other, children infer that there could be an inclusion relation but they have no way to tell which way it should go, so some include A in B, and some B in A.

Children rely on contrast in context to make inferences about the most probable reference for a newly introduced word. For example, if they already know what the object they are attending to is called, they are more likely to infer that a new term denotes a subordinate, a part, or some other property of it (Taylor and Gelman, 1989). This propensity was exploited directly in studies of whether children could decide in context whether a new word was intended to denote an object or an activity. Young 2-year-olds were presented with the same object doing different actions, with one action labeled with the new term, or else several objects, one labeled with the new term and all doing the same action. The children readily inferred that the new word denoted an activity in the first case and an object in the second (e.g., Tomasello, 2002).

Young children are also able to discern the intended from the accidental. When shown various actions being demonstrated, infants aged 18 months imitated intended actions (marked by utterances like *'There'*) more frequently than unintended ones (signaled by utterances like *'Oops'*). By age 2, young children know to ignore errors in wording, for example, and attend only to the final formulation of what someone is saying. In one study, for example, children were taught a word for a set of objects; then the experimenter exclaimed, "Oh, I made a mistake: these aren't As, they're Bs" and proceeded to teach the word B in place of the earlier A. When tested, even children who were just 2 years old knew that they did not know what A, the first word, meant (e.g., Clark and Grossman, 1998).

All the inferences presented so far have been overt inferences about unfamiliar word meanings, made on the spot by children exposed to the new words.

Yet, although adults make clear offers of new words, marking them as new by introducing them in formulaic deictic frames (e.g., *This is a . . .*), with utterance-final stress, many of the other words they use will be unfamiliar to very young children. How do children assign meanings to all those words? The answer lies in the covert use of Roger Brown's (1958) "original word game." Basically, the child notices an unfamiliar word, makes inferences in context about its probable meaning and acts on that, and then adjusts those inferences in light of the adult's responses. Consider these scenarios by way of illustration:

- (a) Young child watching parent in the kitchen, with several drink containers on the counter
 Mother (to older sibling): Hand me that mug, will you?
 (Child, wondering what a mug is, watches sibling pick up a mug)
 Mother: Thanks
 (Child infers for now that *mug* denotes something that has a handle, is a solid color, and is made of ceramic)

Sometimes, the inferences that children make are informed slightly more directly by the parent's direct responses, as in (b).

- (b) Young child holding two plastic animals, a cat and a dog
 Father: Can you give me the spaniel?
 (Child, uncertain what spaniel means, holds out the cat)
 Father: No, the spaniel please.
 (Child infers that *spaniel* must refer to a kind of dog rather than a kind of cat, and so hands over the plastic dog instead)

In both cases, the child makes preliminary or tentative inferences that can then be adjusted or changed in light of adult follow-up utterances, further exposures in other contexts, and additional, often explicit information about inclusion, parts, properties, or functions. Of course, inferences like these can also be made about terms for actions, relations, and states, as well as about those for objects, parts, and properties.

Pragmatics and Meaning

In the conversational exchanges considered so far, adult and child both follow the cooperative principle characterized by Grice (1989), as seen by their observation of joint attention, physical co-presence, and conversational co-presence. In addition, each participant in the exchange must add to common ground and keep account of the common ground that has been accumulated so far (H. Clark, 1996). All of this requires that speakers keep careful track of

the intentions and goals being conveyed within an exchange (Tomasello, 1995; Bloom, 2000).

Infants are attentive to nonlinguistic goals very early. For example, if 14-month-olds are shown an unusual action that achieves a goal – for example, an adult bending down to touch a panel switch with her forehead – they imitate it. If 18-month-olds watch an adult try and fail to place a metal hoop on a prong, the infants will produce the action successfully, even though they have never seen it completed (Meltzoff, 1995). That is, infants infer that the adult intended to turn on the light or intended to hang up the hoop. Intentions are what is critical, Meltzoff demonstrated, not just observation of the relevant actions, because infants do not re-enact these events when the actions are performed by a mechanical hand.

In much the same way, infants attend to the words that adults use. Upon hearing a word, they infer that the speaker is referring to the entity physically present in the locus of joint attention. If instead the speaker produces a different word, they infer that the speaker is now referring to something else and therefore has a different goal in speaking. That is, each linguistic expression chosen indexes a different intention, thus exemplifying the speaker's reliance on contrast, as well as on conventionality (Clark, 1993). This recognition then licenses young children to use words to express their intentions and in this way to convey specific goals. Adult usage provides the model for how to do so within conversational exchanges.

Infants also grasp quite early that the words used to express certain meanings are fixed and conventional. For example, they know that adults who wish to refer to a squirrel use the term 'squirrel' or to refer to a sycamore tree use the term 'sycamore,' and so on. As a result, when they notice adults who fail to use 'squirrel' when looking at a squirrel, but instead use another expression, they can readily infer that the speaker must therefore mean something else. In effect, young children, just like adults, assume that if the speaker intends to talk about a squirrel, he will use the conventional term for it. If instead, he uses something else, then he must intend to convey some other meaning.

As a result, in situations where children already know terms for some of the objects they can see, they expect the adult to use a familiar term for any familiar object. If the adult instead produces an unfamiliar term, in the presence of an unfamiliar object, they will infer that he intended to refer to the object for which they do not yet have a term. So they use contrast, together with the assumption that conventional terms always take priority, to interpret the speaker's intentions on such occasions. The result is that they consistently assign unfamiliar terms to as-yet unnamed objects or actions. This pragmatic

strategy for interpreting intentions and thereby making a first assignment of meaning to an unfamiliar word helps young children in many settings. Take the case of an adult looking at a single familiar object that is well known to the child. The adult, clearly talking about that object, does not use the expected conventional term. What can the child infer from that? There are two common options: (1) the unfamiliar expression denotes a superordinate or subordinate category, or (2) it denotes a part or property of the familiar object. Then, the remainder of the utterance can typically provide the child with important clues about the correct inference. For example, production of a familiar term for a known object is typically followed by a part term accompanied by a possessive pronoun (as in *his ear*), whereas such expressions as *is a kind of* or *is a* are associated with assignments to class membership in a superordinate category (Clark and Wong, 2002; Saylor and Sabbagh, 2004). Use of a verb like *looks* or *feels* (as in *it looks smooth, it feels soft*) often accompanies the introduction of property terms, and when the unfamiliar term is introduced before the familiar one with *kind of* (*a spaniel is a kind of dog*), the child readily infers that the new term, here *spaniel*, designates a subordinate category. Finally, children as young as age 2 rely on a combination of syntax cues and physical co-presence in identifying generic noun phrases; for example, when asked something like *What noise do dogs make?* with just one dog in sight.

What these findings indicate is that even very young children are highly attentive to the locus of joint attention and to whatever is co-present physically and conversationally. When one adds in whatever linguistic knowledge children have already built up about word meanings and constructions, it becomes clear that they have an extensive base from which to make inferences about possible, plausible meanings of unfamiliar words. This holds whether the words are presented explicitly as ‘new’ by adult speakers or whether children simply flag them *en passant* as unfamiliar and therefore in need of having some meaning assigned.

At the same time, young children may have a much less firm grasp on the meanings of many of their words than adult speakers, and incidental or even irrelevant pragmatic factors may affect their interpretations and responses. Take the case of the Piagetian conservation task where the experimenter ‘checks up’ on the 5- or 6-year-old near-conservers’ answer by asking, for the second time, whether the amount that has just been transferred to a new container or transformed into a different array “is still the same.” Children on the verge of conserving typically change

their initially correct answers from ‘yes’ to ‘no’ at this point. They do so because, pragmatically, asking the same question a second time signals that the initial answer was unsatisfactory (Siegal, 1997).

Another Approach

In another approach to the acquisition of lexical meaning, some researchers have proposed that the task is so complex for young children that they must start out with the help of some *a priori* constraints. These constraints are designed to limit the kinds of meanings children can attribute to new words. What form would these constraints take, and what evidence is there for them?

Among the constraints proposed are whole object – ‘Words pick out whole objects’ – and mutual exclusivity: ‘Each referent is picked by just one word’ (e.g., Markman, 1989). The whole object constraint predicts that young children should assume that any unfamiliar word picks out a whole object and not, for example, a part or property of that object. The mutual exclusivity constraint predicts that young children should assume that an unfamiliar word must pick out something other than whatever has a name that is already known to the child. So this constraint predicts that children will systematically reject second terms they hear apparently applied to an already labeled referent, as well as fail to learn second terms.

The predictions from these and other constraints have been tested in a variety of word-learning experiments where the target referents are objects. In fact, the whole object and mutual exclusivity constraints apply only to words for objects, so they would have infants treat all unfamiliar words as if they designated only objects and never actions, relations, or properties. How do such constraints work, as they conflict with many properties of word meanings? For example, mutual exclusivity would cause children to not learn inclusion relations in taxonomies because they would need to apply two or more terms to the same referent category in learning that an X can be called a *dog*, specifically a subtype called a *spaniel*, and that a dog is also a kind of *animal*. The whole object constraint would cause children to not learn terms for parts and properties. It would militate against children learning any terms for activities or relations.

One could propose that such constraints apply only in the early stages of acquisition, after which they are overridden. However, then one has to specify what leads to their being overridden; in other words, what the necessary and sufficient conditions are for each constraint to be dropped so children can start to learn

words for activities and relations, say, from adult usage, or words for parts and properties, as well as words for objects. Under this view of meaning acquisition, children could start out observing the various constraints and then drop each one at a certain stage in development so as to be able to learn other kinds of meanings up to then blocked by the constraints. In short, children should at first ignore much of what their parents say about words and word meanings and reject second labels whenever they are offered to mark a different perspective, for example. They should also look for words only to pick out objects, mistakenly assigning any that might, in context, seem to be designating categories of actions or relations as words for objects instead.

Is this a realistic picture of development? No, because it calls for selectively ignoring or rejecting a large amount of what adults do with language as they talk about the world to their children, offer them words for objects and events in the locus of joint attention, and provide extensive commentary on parts, properties, motion, and functions associated with specific category members. The constraints approach ignores conditions imposed on conversational exchanges, such as joint attention, and physical and conversational co-presence, and what they contribute to assigning meaning. It also conflicts with adult usage, which offers a range of perspectives on specific objects and events. A piece of fruit can be just that, *fruit*, or it can be *an apple*, *dessert*, or *a snack*, depending on the perspective chosen (Clark, 1997). Yet, these factors must all be taken into account in both designing and interpreting studies of meaning acquisition.

Sources of Meanings

Children draw on conceptual categories already known to them and on information offered in context, both nonlinguistic and linguistic, when they assign a first meaning to new words. Infants build up and organize conceptual categories of the objects, relations, and events they observe months before they try to use words to evoke the relevant categories. As they assign candidate meanings, they rely on these conceptual categories to connect category instances and words as they start in on language (Slobin, 1985). However, because languages differ, children learn, for purposes of talking, to attend automatically to some aspects of events and ignore others; for example, whether an action is complete or not or whether the speaker witnessed an event for herself or simply heard about it. It is therefore important to distinguish between conceptual knowledge about events and the

knowledge speakers draw on when they talk about those events (Slobin, 1996).

Children try to make sense of what the adult wants. This means relying on any potentially useful source of information for interpreting and responding to adult utterances. What children know about the conceptual categories that appear to be at the focus of joint attention seems to provide initial strategies for coping when they do not yet understand all the words. The physical and conversational contexts, with joint attention, identify the relevant 'space' in which to act. This holds just as much for responding to half-grasped requests as for direct offers of unfamiliar words. Children attend to what is physically present, to any familiar words, and to any conceptual preferences. These preferences may include choosing greater amounts over lesser ones, assuming that the first event mentioned is the first to occur, and exchanging one state of affairs for another (Clark, 1997). Such coping strategies may be consistent with the conventional meanings of certain words, so children will appear to understand them when in fact they do not. The match of coping strategies and meanings offers one measure of complexity in acquisition: Matches should be simpler to acquire than cases of mismatch.

Children can draw on what they already know about objects and events, relations, and properties for their world so far. Their current knowledge about both conceptual categories and about their language at each stage offers potential meanings, in context, assignable to unfamiliar words. These preliminary meanings can be refined, added to, and reshaped by adult usage on subsequent occasions. This way, children learn more about the meanings that about each word, the contrasts relevant in particular semantic domains, and the number of terms in a domain that have to be distinguished from one another. To succeed in this effort, children have to identify consistent word uses for specific event-, relation-, and object-types. They have to learn what the conventions are for usage in the speech community where they are growing up (e.g., Eckert, 2003).

Summary

As children learn new words, they rely on what they know so far – the conceptual and linguistic knowledge they have already built up – to assign them some meaning in context. These initial meanings draw equally on their own conceptual categories and on adult patterns of word use within the current conversational exchange. In effect, joint attention, along with what is co-present physically and

conversationally, places pragmatic limits on what the meaning of an unfamiliar word is most likely to be. In addition, adults often provide further information about the referent object or action, linking the word just offered to other words for relevant properties and actions, and thereby situating the new word in relation to terms already known to the child. This framing by adults for new word meanings licenses a variety of inferences by the child about what to keep track of as relevant to each particular word meaning (Clark, 2002). Adults here are the experts and constitute both a source and resource for finding out about unfamiliar word meanings.

Meaning: Overview of Philosophical Theories

R M Martin, Dalhousie University, Halifax, NS, Canada

The Direct Reference Theory

It is obvious that an important fact about language is that bits of it are systematically related to things in the world. ‘Referential’ theories of meaning hold that the meaning of an expression is a matter, somehow, of this connection.

The most immediately plausible application of this theory is to the meaning of proper names: the name ‘Benedict Spinoza’ is connected to the philosopher, and this fact appears to exhaust the meaning of that name. The other names – ‘Benedictus de Spinoza,’ ‘Baruch Spinoza,’ and ‘Benedict d’Espinosa’ – mean the same because they are connected to the same person.

But even in the case of proper names, problems arise. For example, consider proper names with non-existent references: ‘Santa Claus.’ If the meaning of a proper name is constituted by nothing but its relationship to the bearer of that name, then it follows that ‘Santa Claus’ is meaningless; but this seems wrong, because we know perfectly well what ‘Santa Claus’ means, and we can use it perfectly well, meaningfully. Another example would be the two proper names applied to the planet Venus by the Ancient Greeks, who were unaware that it was the same planet that appeared sometimes in the evening sky, when they called it ‘Hesperus’ and sometimes in the morning sky, when they called it ‘Phosphorus.’ Because these two names in fact refer to one and the same object, we should count them as having exactly the same meaning. It would appear to follow that someone who knew the meaning of both names would recognize that the meaning of one was exactly the same as the meaning of the other, and therefore would be willing to apply them identically. But the Greeks, when seeing Venus in the morning sky, would apply ‘Phosphorus’ to it, but refuse to apply ‘Hesperus.’ Does it follow that they did not fully understand the meanings of those terms? That is an implausible conclusion, since these are terms of the ancient Greek language: how could the most competent speakers of that language fail to understand the meanings of two terms in that language? It looks much more plausible to say that the fact that Hesperus and Phosphorus are identical is not a consequence of the meanings of those words. So meaning is apparently not exhausted by reference. (This example and this argument were originated by Frege.)

But here is a second sort of difficulty for the reference theory. Even if it could do a plausible job of explaining the meaning of proper names, it is not at all clear what it should do with other elements of language. Proper names, after all, make up only a small part of language, and an atypical part, insofar as meaning is concerned, at that; one does not find them in most dictionaries, for example.

Consider whether this sort of approach to meaning might be extended to linguistic items other than proper names. It is a short step from there to more complex, less direct ways of referring, for example, ‘the Amsterdam-born author of the *Ethics*.’ If this definite description gets its meaning by its reference, then since it refers to Spinoza again, it must mean the same as those other names. But a problem immediately arises here, similar to the ‘Hesperus/Phosphorus’ worry. One might understand the meaning of ‘Benedict Spinoza’ perfectly, it seems, without knowing some facts about the philosopher, for example, that he was born in Amsterdam and wrote the *Ethics*; and, as a result, although one understood ‘the Amsterdam-born author of the *Ethics*’ he or she would not know that this referred to Spinoza. A similar problem arises with the ‘Santa Claus’ worry: ‘the present king of France’ is surely meaningful, although it is without reference (Russell’s famous example).

Still other linguistic elements provide greater difficulty for a reference theory. How, for example, is the meaning of the predicate ‘is wise,’ occurring, for example, in ‘Spinoza is wise,’ to be explained in terms of reference? Particular wise objects exist, to be sure – Spinoza for one. But clearly it is not helpful to think that ‘is wise’ here gets its meaning merely by referring to Spinoza again – which would add nothing – or to some other wise person – which seems irrelevant. And what if that sentence were false (but meaningful), and Spinoza were not among the wise things: what would ‘is wise’ refer to then? More likely ‘is wise’ refers to a set of things – the wise individuals (Spinoza, Socrates, Bertrand Russell, etc.). But the sentence clearly tells us more than that Spinoza belongs to the group Spinoza, Socrates, Bertrand Russell, etc. It refers not to that group, it seems, but rather to the property that is necessary for inclusion in that group: wisdom. It is controversial whether we really need to populate our universe with strange objects such as ‘properties’ and ‘universals’; but, in any case, even if they do exist, it’s not clear that ordinary predicates refer to them. For example, ‘wisdom’ may be the name of a particular thing, referred to in the sentence, ‘Wisdom appeals to Francine,’ but it is much less clear that this thing is referred to in the sentence ‘Spinoza is wise.’ A similar

difficulty is posed by common nouns, e.g., ‘philosopher.’ It does not seem that we could explain the meaning of this element in the sentence ‘Spinoza is a philosopher’ by claiming reference to a particular philosopher, the class of philosophers, or philosopher-ness.

Furthermore, reference has nothing to do with grammatical structure, which one would think is an important part of the meaning of any sentence. These two sentences, ‘Jane loves John’ and ‘John loves Jane,’ make the same references (to Jane, John, and loving, perhaps) but they surely mean something very different. A sentence conveys more than a series of references. It does not merely point at Jane, John, and the property of loving; in addition, it makes the claim that Jane loves John (or vice versa).

Meaning as Truth Conditions

Perhaps a more promising way to extend the reference theory for common nouns, predicates, and other linguistic elements is to think of them as functions. Consider the analogy with arithmetic: 5, 13, -9, and so on are the names of numbers (whatever they are), but $x/3 = 9$ is a function from numbers to a ‘truth value.’ With ‘27’ as the argument, its value is TRUE. With ‘16’ as the argument, its value is FALSE. Its meaning consists in the systematic way in which it pairs arguments with truth values. Now consider the systematic way ‘x is wise’ relates arguments to truth values. Substitute the proper name of certain things (any of the wise things) and the value is TRUE. Substitute the proper name of other things and the value is FALSE. The systematic way in which arguments and values are related in this case (it seems) exhausts the meaning of ‘is wise.’ Philosophers have proposed similar ways to deal with other linguistic elements. For example, adverbs might be regarded as functions taking a predicate as ‘argument’ and yielding a predicate as ‘value.’

This amendment in the spirit of the direct reference theory considerably extends its power and explains the function, basically in terms of reference, of various parts of language that do not by themselves refer. Partially because some of the functions in this approach have TRUE and FALSE as values, it was proposed that these truth values be considered the referents of sentences. (This move has seemed implausible to many, however: what are these things called truth values?)

In the 1930s, Alfred Tarski proposed a definition of ‘truth’ that some philosophers thought would be the basis of a good theory of meaning. Tarski’s proposal was that what would constitute a definition of TRUE for a language *L* would be a complete list of

statements giving the truth conditions for each of the sentences in *L*. So one of these statements defining truth-in-English would be ‘*Snow is white*’ is true in English if and only if snow is white. (This may appear ludicrously trivial, because the sentence whose truth conditions are being given, and the reference to the truth condition itself, are in the same language. Of course, if you did not know what made ‘Snow is white’ true, this statement would not tell you. But that is not a problem with Tarski’s view in particular: no statement of a theory would be informative to somebody who didn’t speak the language in which the theory was stated.)

Now, when we know the truth-conditions for a sentence, then do we know its meaning? Once you know, for example, what it takes to make ‘Snow is white’ true, then, it seems, you know what that sentence means. And what it takes, after all, is that snow be white.

Obviously what one learns when one learns the meaning of a language cannot be the truth conditions of each sentence in the language, one at a time, because there are an infinite number of sentences. What is learned must be the meanings of a finite number of elements of sentences, and a finite variety of structures they go into. In the Tarskian view, then, the semantic theory of a language consists of a large but finite number of elements (words, perhaps), together with composition rules for putting them together into sentences and information sufficient for deriving the truth conditions for each of a potentially infinite number of sentences.

One might object that this elaborate theory could not be what people know when they know what their language means. But perhaps providing this is not the purpose of a semantic theory (or a theory of anything). Baseball players are adept at predicting the path of a ball but only rarely are familiar with Newtonian theory of falling bodies.

The idea here is attractive. If you know what sort of world would make a sentence true, then it seems that that is all it would take for you to know what that sentence means. This idea (though not particularly through Tarski’s influence) was the basis of the ‘logical positivist’ theories of meaning and of meaningfulness. Logical positivists enjoyed pointing out that Heidegger’s famous assertion “*Das Nicht nichtet*” (‘The nothing nothings’) was associated with no particular ways the world might be that would make it either true or false, and concluded that this statement, along with many others in metaphysics (e.g., McTaggart’s assertion that time is unreal), were meaningless. But it seemed that baby and bathwater alike were being flushed down the drain. Coupled with a rather narrow and ferocious empiricism, this

criterion ruled out as meaningless a number of assertions that were clearly acceptable. What empirical truth conditions are there **now** for statements about the past, or for assertions about invisible subatomic particles? But this may be a problem more about the logical positivists' narrow empiricism than about their theory of meaning/meaningfulness. More germane here is the problem that many perfectly meaningful sentences have no truth conditions because they're neither true nor false: 'Please pass the salt,' for example.

Sense and Reference

Because of the Hesperus/Phosphorus problem mentioned above, Frege rejected the idea that the meaning of an expression is the thing it refers to. So Frege distinguished the thing to which a symbol referred (in his words, the *Bedeutung*, the 'referent' or 'nominatum') from what he counted as the meaning (the *Sinn*, usually translated as the 'sense') of the symbol, expressed by the symbol. The sense of a symbol, according to Frege, corresponded to a particular way the referent was presented. It might be called the 'way of thinking about' the referent. While his theory separated meaning from reference, nevertheless it can be considered a 'mediated reference theory': senses are ways a reference would be encountered, ways of getting to things from the words that refer to them. But it is the reference of included terms, not their sense, that determines the truth value of the sentence.

Frege's approach led him to a problem with sentences such as these:

- (1) Fred said, "Venus is bright tonight."
- (2) Fred believes he's seeing Venus.

Both sentences include examples of 'opaque context,' a part in the sentence in which substitution of a co-referring term can change the truth value of the sentence. In each of these sentences, substituting 'the second planet from the sun' for 'Venus' may make a true sentence false, or a false one true. In (1), an example of 'direct discourse,' if Fred's very words did not include 'the second planet from the sun,' then that substitution can make a true sentence into a false one. That substitution in (2) may result in a false sentence if Fred believes that Venus is the third planet from the sun. Frege's solution to this problem is to stipulate that in direct discourse – word-for-word quotation – the expression quoted refers to 'itself,' rather than to its usual referent (in this case, Venus). And in belief contexts and some other opaque contexts, expressions refer to their 'senses,' not to their usual referents.

But what, exactly, are these 'senses'? First, it is clear that Frege did not intend them to be the ideas anybody

associates with words. Frege's 'senses' are objective: real facts of the language whose conventions associate senses with its symbols. One may have any sort of association with a bit of language, but the conventions of the language specify only certain of them as meaning-related. (Therefore, Lewis Carroll's Humpty Dumpty does not succeed in meaning 'There's a nice knock-down argument for you' with 'There's glory for you,' even though he insists "When I use a word it means just what I choose it to mean – neither more nor less.") But why not admit that in addition to the public languages there can be 'private' ones with idiosyncratic senses? More will be said about this later.

But second, neither can 'senses' be characteristics of the things referred to: for then, whatever is a sense of 'Hesperus' would be a sense of 'Phosphorus.' Furthermore, there appear to be symbols in a language that have sense but no reference: 'the present king of France' and 'Atlantis' are examples. Reference-less terms pose a problem for Frege. Should he consider them words with sense but no reference? If so, then how can they figure in sentences with a truth-value? (This is similar to the 'Santa Claus' problem.)

A promising approach seems to be to say that the sense of a term 'T' consists of those characteristics judged to be true of things that are called 'T' by competent speakers of the language. But this immediately creates a problem with proper names. If ordinary proper names have senses – associated characteristics that are the way of presenting the individual named, associated conventionally with that name by the language – then there would be corresponding definitional (hence necessary) truths about individuals referred to by proper names. But this is problematic. The sense of a name applying to one individual cannot be the sense of the name of any other individual, because senses are the way terms pick out their designata. So the characteristics associated with a name would have to constitute that individual's 'individual essence' – characteristics uniquely and necessarily true of that individual. But many philosophers have doubted that there are any such characteristics. Even if we can find characteristics that uniquely designate an individual, Kripke (1972) influentially argued that these characteristics are never necessary. Suppose, for example, that 'Aristotle' carries the sense 'Ancient Greek philosopher, student of Plato, teacher of Alexander the Great.' It would follow that this determined the referent of 'Aristotle'; so if historians discovered after all that no student of Plato's ever taught Alexander the Great, then 'Aristotle' would turn out to be a bearer-less proper name, like 'Santa Claus.' But this is not how the proper name would work. Instead,

we would just decide that Aristotle did not teach Alexander after all. Kripke argues that all sentences predicating something of a proper-named individual are contingent, so proper names do not have senses. But, of course, they are meaningful bits of language.

This problem may apply even more broadly than merely to proper names. Consider the meaning of the term ‘water.’ Back before anyone knew the real properties of what made water water – i.e., its chemical constitution – competent speakers applied the term to any colorless, odorless liquid. But they were sometimes wrong, because the characteristics then used to distinguish proper and improper applications of the term, although they happened to pick out water on the whole, were not the genuinely necessary and sufficient conditions for something to be water at all. In those days, then, the real sense of the word was totally unknown and unused by any competent speaker of the language.

Quine argued that Frege’s senses lack what is necessary for well-behaved theoretical objects. We have no idea, for example, of their identity conditions: is the sense of this word the same as the sense of that? More about Quine will be discussed in the final section of this article.

The Idea Theory

The theories discussed so far consider what linguistic elements mean, but other classical theories have concentrated on what people mean by bits of language.

Words, Locke argued, are used as ‘sensible marks’ of ideas; the idea corresponding to a word is its meaning. This has a certain amount of intuitive plausibility, in that non-philosophers think of language as a way of communicating ideas that is successful when it reproduces the speaker’s idea in the hearer’s mind.

The ‘idea theory’ of meaning received its fullest expression in conjunction with British Empiricist epistemology. For the classical empiricists, our ideas were copies of sense-impressions – presumably similar to the sense experiences themselves, except dimmer. These mental representations served us as the elements of thought and provided the meanings for our words.

However, problems with this theory are obvious. For one thing, not every such association is relevant to meaning. For example, the word ‘chocolate’ makes me picture the little shop in Belgium where I bought an astoundingly impressive chocolate bar. But although one might want to say, in a sort of loose way, that that’s what ‘chocolate’ means to me, it doesn’t seem to be a real part of the word’s meaning. Someone else could be completely competent in using that word without any mental pictures of Belgium.

Also, there are some meaningful terms that seem to be associated with no mental imagery, for example, ‘compromise.’ The problem of the meaning of ‘unicorn’ is solvable: images of a horse’s shape and an antelope’s horn can be mentally pasted together to provide a representation; but there are other problems. My image of my cat Tabitha might picture her facing right; but I’m to use this also to identify her as the bearer of that name when she’s facing left; so the mere association of a word with an image is not enough to give that word meaning. There must also be some procedure for using that image. Common nouns (‘dog’) could stand for any and all dogs, whereas the meaning of ‘dog’ was presumably a particular image of a particular dog. More of a theoretical mechanism is needed to explain why this image stands for Fido and Rover but not for Tabitha. And other sorts of words – logical words, prepositions, conjunctions, etc. – raise problems here too: how could sensory experiences be the source of **their** meaning?

A more recent concern about the idea theory arose from the fact that the ideas that gave bits of language their meaning were private entities, whereas the meanings of a public language were presumably public. Clearly I would learn the word ‘cat’ by hearing you use the word in the presence of cats, but not in their absence; but according to the idea theory, I would have learned it correctly when my private image matches yours – something that is impossible for either of us to check. What we can check – identical identifications of objects as cats and non-cats – does not ensure identical private imagery and (according to the idea theory) has nothing directly to do with the meaning we invest ‘cat’ with anyway. Wittgenstein’s ‘private language argument,’ deployed against the idea theory, was considered devastating by many philosophers. Very briefly put, this argument is that the meaning of a public bit of language could not be given by a supposedly necessarily private item, such as a mental representation, because this would make impossible any public check – any real check at all – on whether anyone understood the meaning of a term; and without the possibility of a check, there was no distinction between getting the meaning right and getting it wrong.

Meaning as Use

Wittgenstein’s hugely influential suggestion was that we think instead of sentences as “instruments whose senses are their employments” (1953: 421). Starting in the 1930s and 1940s, philosophers began thinking of the meaning of linguistic items as their potential for particular uses by speakers and attempting to isolate and describe a variety of things that people do with

words: linguistic acts, accomplished through the use of bits of language. One clear theoretical advantage of this approach over earlier ones was its treatment of a much wider variety of linguistic function. Whereas earlier approaches tended to concentrate on information giving, now philosophers added a panoply of other uses: asking questions, giving orders, expressing approval, and so on. This clearly represented a huge improvement on the earlier narrower views, which tried to understand all the elements of language as signs – representations – of something external or internal.

Austin distinguished three kinds of things one does with language: (1) the ‘locutionary act,’ which is the utterance (or writing) of bits of a language; (2) the ‘illocutionary act,’ done by means of the locutionary act, for example, reporting, announcing, predicting, admitting, requesting, ordering, proposing, promising, congratulating, thanking; and (3) the ‘perlocutionary act,’ done by means of the illocutionary act, for example, bringing someone to learn *x*, persuading, frightening, amusing, getting someone to do *x*, embarrassing, boring, inspiring someone. What distinguishes illocutionary acts is that they are accomplished just as soon as the hearer hears and understands what the utterer utters. It is clear that the illocutionary act is the one of these three that is relevant to the meaning of the utterance. The performance of the act of merely uttering a sentence obviously has nothing to do with its meaning. Neither does whatever perlocutionary act is performed: you might bore someone by telling her about your trip to Cleveland or by reciting 75 verses of *The fairie queen*, but the fact that both of these acts may serve to bore the hearer does not show that they are similar in meaning. But similarity in meaning is demonstrated by the fact that two different locutionary acts serve to accomplish the same illocutionary act. For example, ‘Do you have the time?’ and ‘What time is it, please?’ perform the same illocutionary act (a polite request for the time) and are thus similar in meaning.

However, this approach does not deny that what the other theories concentrated on is a significant part of language. In Austin’s classification, one part of many locutionary acts is an act of referring; when I say, “Aristotle was the student of Plato,” I’m probably performing the illocutionary act of informing you, but I’m doing that by means of the locutionary act of referring to Aristotle and Plato. And clearly many linguistic acts include ‘propositional content’: one reports, announces, predicts, admits, requests, orders, proposes, promises, and so on, ‘that *p*,’ so it seems that inside this theory we would need an account of the way any of these linguistic acts correspond to actual or possible states of the world.

A recent influential theory from Donald Davidson responds to these needs by combining, in effect, speech act theory with Tarskian semantics. According to Davidson’s proposal, the list of truth conditions for each assertion in a language provides an account of the language’s semantics – at least, of the propositional content of sentences in the language: what a statement, prediction, assertion, question, etc., states, predicts, asserts, asks, etc. This explains what is shared by ‘The light is turned off,’ ‘Turn off that light,’ ‘Is the light turned off?’ and so on. But secondly, according to Davidson, a theory of meaning needs a ‘mood indicator’ – an element of the sentence that indicates the use of that sentence – e.g., as a statement, request, or question.

Quine’s Skepticism

Quine’s skepticism about meanings was among the most important 20th-century developments in the philosophy of language. Here is one way of approaching his position. Imagine a linguist trying to translate a tribe’s language. Suppose that the tribesmen said “*gavagai*” whenever a rabbit ran past. Does ‘*gavagai*’ mean ‘lo, a rabbit!’? The evidence might as well be taken to show that ‘*gavagai*’ asserts the presence of an undetached rabbit part, a temporal slice of a rabbit, or any one of a number of other alternatives, including even ‘Am I ever hungry!’ or ‘There goes a hedgehog!’ (if the tribesmen were interested in misleading you). Quine called this the ‘indeterminacy of translation.’ But, we might object, couldn’t further observation and experimentation decide which of these alternatives is the right interpretation? No, argued Quine, there are always alternatives consistent with any amount of observation. But, we might reply (and this is a more basic objection), what that shows is that a linguist never has absolutely perfect evidence for a unique translation. This is by now a familiar (Quinian) point about theory: theory is always to some extent undetermined by observation. In any science, one can dream up alternative theories to the preferred theory that are equally consistent with all the evidence to date. But in those cases, isn’t there a right answer – a real fact of the matter – which, unfortunately, we may never be in a **perfect** position to determine, because our evidence must always be equivocal to some extent? At least in the case of meaning, argued Quine, the answer is no, because for Quine, linguistic behavior is all there is to language, so there are no hidden facts about meaning to discover, with linguistic behavior as evidence. So meanings are not given by ideas in the head, Fregean senses, or anything else external to this behavior.

A similar sort of position was argued for more recently by Kripke (1982). Imagine that

someone – Fred – has used a word ‘W’ to refer to various things, A, B, and C. Now he encounters D: is that referred to by ‘W’? One wants to say: if D is like A, B, and C, then Fred should go on in the same way and apply ‘W’ to D. But Kripke argues that there is no fact about Fred’s intentions or past behavior – no fact about what he means by ‘W’ – that would make it correct or incorrect for him to apply ‘W’ to D. Neither is there, in the external world, a real sufficient (or insufficient) similarity of D to A, B, and C that make it correct (or incorrect). The only thing that would make that application correct or incorrect is what a community of speakers using that word would happen to agree on.

But does anti-realism about meaning really follow from these considerations? Suppose that Quine and Kripke are right, and all there is to language is social behavior. But maybe this does not imply that meanings are unreal. When we consider an action as social behavior, after all, we do not think of it (as Quine, in effect, did) merely as bodily movements. There are facts about the social significance of the behavior, above and beyond these movements, that give the movement its social significance. Perhaps it is these facts that would make one linguistic theory rather than another correct – that determine the meaning of the noises made by Quine’s natives, and whether Fred is following the linguistic rule when he applies ‘W’ to D. Language is a tool we know how to use, and the real meaning of our utterances is what we know when we know how to use that tool.

Meaning: Procedural and Conceptual

D Blakemore, University of Salford, Greater Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

The distinction between procedural and conceptual meaning resulted from the attempt to reanalyze Grice’s (1989) notion of conventional implicature in relevance theoretic terms, or, more generally, from

the attempt to provide a cognitive reanalysis of the distinction drawn between truth conditional and non-truth conditional meaning (see Grice, 1989; see **Implicature**). However, soon after its introduction (Blakemore, 1987), it was shown that the relevance theoretic distinction was not coextensive with the distinction between truth conditional and non-truth conditional meaning, and thus represented a departure from the approach to semantics that

underlies Grice's notion of conventional implicature. While there is a range of phenomena that can be analyzed in terms of the conceptual–procedural distinction, the emphasis in pragmatics has mostly centered on its application to the analysis of so-called 'discourse markers'. It has to be said, however, that the term *procedural* is not always used in the same way, and that the distinction between conceptual and procedural encoding is not always drawn within a relevance theoretic framework. In argumentation theory, any expression which has an argumentative function is said to encode procedural meaning (Moeschler, 1989). According to this criterion, *because* is procedural; however, it is not procedural according to the relevance theoretic definition outlined below. Fraser (1996, 1998) has used the term *procedural* to describe the meaning of any expression with an indicating function, where *indicating* is intended in its speech act theoretic sense, in which it contrasts with *saying* or *describing*. Because the relevance theoretic distinction is not coextensive with the traditional distinction between truth conditional and nontruth conditional meaning, it is not surprising that there are expressions which are procedural according to Fraser but conceptual according to the relevance theoretic definition – e.g., *as a result*. This article will focus on the relevance theoretic distinction, showing, on the one hand, how it derives from a relevance theoretic view of linguistic semantics, and on the other, how the principle of relevance provides an explanation for the fact that languages have developed means for encoding procedures (see **Relevance Theory**). It will then turn to the way in which procedural encoding has been applied in the analysis of discourse markers or connectives, and the questions this type of analysis raises.

Relevance Theoretic Semantics

Grice's (1989) notion of conventional implicature was a means of maintaining a definition of *what is said* in which linguistic meaning coincides with truth conditional content. While he accepts that the suggestion carried by *therefore* in (1) is linguistically encoded, he does not wish to allow that in his "favoured sense of 'say,' one who utters (1) would have *said* that Bill's being courageous follows from his being a philosopher" (1989: 21):

- (1) Bill is a philosopher and he is, therefore, brave.

Grice's solution to the problem posed by nontruth conditional linguistic meaning was to modify his definition of *what is said* so that it applied only to the performances of so-called *central* speech acts, and not to the performances of *noncentral* speech acts indicated by expressions such as *therefore* (see **Speech Acts**).

However, as Sperber and Wilson (1995) and Carston (2002) have shown, the assumption that linguistic meaning coincides with the truth conditional content of the utterance cannot be justified, because the propositional content of utterances is underdetermined by their linguistic properties. While the thoughts communicated by utterances may have truth conditions, it cannot be said that linguistic form encodes thoughts. Linguistic meaning is an input to the pragmatically constrained inferential processes that use contextual information to deliver thoughts. The question for linguistic semantics, in this view, is not about the relationship between language and the world but about the relationship between linguistic form and the inferential processes that deliver thoughts.

The distinction between conceptual and procedural encoding derives from the argument that if utterance interpretation involves the construction and inferential manipulation of propositional representations, then it is reasonable to expect two answers to this question. On the one hand, linguistic form can encode the constituents of the conceptual representations that take part in inferential computations, and on the other, it can encode information that makes particular kinds of computations salient. Consider (2a) and (2b), where (2b) could be interpreted as a contextual implication derived in an inference that has (2a) as a premise, or as a premise that has (2a) as a conclusion.

(2a) Tom will be late.

(2b) He is coming from London.

The claim that linguistic meaning can encode procedures is the claim that there are linguistic expressions e.g., – *so* or *after all* in this case – which guide the hearer to the inferential procedure that yields the intended interpretation.

Why Languages Develop Procedural Encoding

It has been argued that the fact that languages have developed expressions which constrain inferential procedures can be explained within relevance theory in terms of the communicative principle of relevance (Sperber and Wilson, 1995). According to this principle, a hearer who recognizes that a speaker has deliberately communicated with her is entitled to assume not just that the utterance is relevant enough (in terms of effects and effort) to be worth her attention, but that it is the most relevant utterance the speaker could have produced, given her interests and abilities. Because the degree of relevance is affected by the amount of processing effort required for the derivation of the intended cognitive effects, this means that the use of an expression that encodes a procedure for

identifying the intended interpreted would be consistent with the speaker's aim of identifying relevance for a minimum processing cost.

Traugott and Dasher (2002) have argued that languages tend to develop procedural constraints on interpretation out of their existing conceptual resources. However, although they agree that there is a distinction between procedural and conceptual (or, as they call it, 'contentful') meaning, their account of how meaning change takes place is based on the assumptions of cognitive semantics and neo-Gricean pragmatics rather than on relevance theoretic pragmatics, and it is not clear that the distinction is drawn in the same way. Moreover, their account assumes that meaning, changes results from the conventionalization of pragmatic inferences, where this is unpacked in (Gricean) terms of the conventionalization of the relation between a linguistic form and the proposition or propositions derived by inference. A relevance theoretic account would approach this process in terms of the conventionalization of an inferential routine or process.

If procedural meaning develops from existing conceptual resources, then it would not be surprising for an expression to encode both a concept and a procedure. Although it has been argued that this possibility has been ruled out in relevance theory, it is consistent with relevance theoretic assumptions, and there have been relevance theoretic analyses (e.g., Blakemore's 1987 analysis of *but*, Nicolle's 1997 and 1998 account of *be going to*, and Wilson's 2004 analysis of expressions such as *few* and *several*) where it is argued that a single form may encode two types of meaning.

The Conceptual–Procedural Distinction and Conventional Implicature

While the notion of procedural encoding was developed as a means of analyzing expressions which encode constraints on the recovery of implicit content – e.g., *therefore*, *so*, *after all* – subsequent investigation suggested that it could be extended to expressions that encode constraints on the recovery of explicit content. Some of these – mood indicators, attitudinal particles – are analyzed as encoding constraints on the inferential processes involved in the recovery of higher-level explicatures. For example, Wilson and Sperber (1993) suggest that the use of *huh* in (3) encourages the hearer to construct the higher-level explicature in (4) (see also Wilson and Sperber, 1988; Clark, 1993):

(3) Peter's a genius, huh!

(4) The speaker of (3) doesn't think that Peter is a genius.

In this case, the equation between procedural meaning and nontruth conditional meaning is maintained, because higher-level explicatures are not regarded as contributing to truth conditional content. However, it has also been suggested that there are expressions, notably pronouns, which should be analyzed as constraints on the proposition expressed, and thus contribute to truth conditional content.

At the same time, it has been argued (Wilson and Sperber, 1993; Ifantidou-Trouki, 1993; Blakemore, 1990, 1996) that expressions such as sentence adverbials or parentheticals which, although they do not contribute to truth conditional content, must be analyzed as encoding concepts. This means that the procedural–conceptual distinction cannot be coextensive with the distinction that underlies Grice's notion of conventional implicature.

If Carston's (2002) conception of linguistic semantics is right, then the fundamental distinction must be the conceptual–procedural distinction rather than the distinction between truth conditional and non-truth conditional meaning. This means that linguistic semantics must include a means of distinguishing conceptual from procedural meaning. Within relevance theory, attention has been drawn to properties that distinguish expressions that encode procedures from those that encode concepts. First, in contrast with concepts, procedures cannot be brought to consciousness (Wilson and Sperber, 1993: 16). This explains why even native speakers find it difficult to judge whether expressions which encode procedures – e.g., *but* and *however* in English or *dakara* and *sorede* in Japanese – are synonymous without testing their intersubstitutability in all contexts. In contrast, even when the definition of a concept proves controversial, speakers can say whether two expressions encode the same concept without having to test whether they can be substituted for each other in every context. If it is difficult for native speakers to make synonymy judgments, then it is not surprising that the translation of expressions that encode procedures is notoriously difficult, particularly since languages do not necessarily conventionalize the same inferential routines. However, the translation of procedural meaning has yet to be investigated systematically.

Second, while expressions that encode concepts can be semantically complex, expressions that encode procedures cannot combine with other expressions to produce semantically complex expressions. Compare (5) with (6):

(5) In total, absolute confidence, she has been promoted.

(6) Sue likes red wine. *Totally however, Mary drinks beer.

Rouchota (1998) has shown that while expressions that have been analyzed as encoding procedures can combine in some way, they do not combine to form complex discourse markers. Compare (7) with (5):

- (7) Sue fell asleep during the lecture. But after all, she had heard it all before.

Procedural Analyses of Discourse Markers

The notion of procedural encoding has been applied to the analysis of a range of nontruth conditional discourse markers in a variety of languages (e.g., Blass, 1990; Itani, 1993; Unger, 1996; Matsui, 2002; Iten, 2000; Blakemore, 2002). However, this work has suggested that the original notion is neither sufficiently fine-grained to capture the differences between closely related but nonintersubstitutable discourse markers (e.g., *but* and *however* or *dakara* and *sorede*), nor sufficiently broad to capture all the ways in which linguistic form can encode information about the inferential computations involved in the interpretation of utterances. As it is defined by Blakemore (1987), procedural encoding is linked to the three cognitive effects defined within relevance theory: contextual implication, strengthening, and elimination. In order to account for the differences between expressions such as *but* and *however*, it has been argued that the notion of procedural encoding must be broadened to include the activation of particular types of contexts. Moreover, it has been suggested that the meanings of some discourse markers (e.g., *well*) may not necessarily be linked to the activation of cognitive effects at all (see Blakemore, 2002).

Future Directions

Procedural encoding has also played a role in the analysis of the role of intonation in interpretation (see Fretheim, 2002; House, 2004). If, as Gussenhoven (2002) has argued, aspects of intonation have become grammaticalized so that certain pitch contours encode arbitrary meanings, then it is plausible that these meanings should be analyzed in terms of instructions for interpretation. However, Wharton's (2003a, 2000b) work on natural codes suggests it may also be possible to generalize the notion of procedural meaning to accommodate phenomena that are on the borderline of language (e.g., interjections) as well as natural or paralinguistic aspects of intonation. Research in this area has yet to be developed, but it seems clear that the scope of procedural encoding extends beyond the analysis of the nontruth conditional discourse markers.

Mentalese

F Egan, Rutgers University, New Brunswick, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

The Basic Hypothesis

Some theorists of mind have claimed that thought takes place in a language-like medium. They have called this language 'Mentalese.' Mentalese has a syntax, a semantics, and a morphology, though discovering these properties of the language of thought will likely require extensive empirical investigation of the mind. Obviously, mentalese does not have a phonology. It is therefore more like written public language than overt speech. And whereas public languages require a pragmatics – a theory of how the language is used by speakers – mentalese, like the machine languages of computers, does not call for one.

Gilbert Harman (1973) offered the following argument for the existence of mentalese: logical relations hold among mental states, and these relations are essential to their role in psychological prediction and explanation. If the belief that *snow is white and grass is green* is true, then the belief that *snow is white* is true. In general, if the belief that *p & q* is true, then the belief that *p* is true. Generalizations of this sort presuppose that beliefs have sentential structure. Some beliefs are conjunctions, others disjunctions, and so on. Beliefs (as well as desires, fears, and the other propositional attitudes) are part of a language-like system.

Harman's argument fails to establish that mental states themselves have logical or sentential structure. The argument trades on the fact that belief ascriptions have sentential structure. We ascribe certain beliefs to subjects using sentences that are conjunctive or disjunctive, but it does not follow that the mental states so ascribed are themselves conjunctions or disjunctions, or that the relations that hold among these mental states are of the sort that hold among sentences (or propositions), that is, that they are logical relations. To assume that they are is just to assume

what is at issue – that thoughts have a language-like structure. In general, one must guard against attributing to thoughts themselves properties of the representational scheme that we use to talk about them.

The hypothesis that thought occurs in a language-like medium is understood as the claim that not only beliefs but also desires and the other propositional attitudes are properly construed as relations to sentences in the inner language. To believe that the conflict in the Middle East will not be resolved is to bear a relation to an inner sentence token that means *the conflict in the Middle East will not be resolved*. To fear that the conflict in the Middle East will not be resolved is to bear a different relation to an internal sentence of the same type. The difference between the believing-relation and the fear-relation is construed as a difference in the processing that the sentence token undergoes in the brain, in other words, as a difference in its functional role. The belief is likely to cause, in certain circumstances, sincere assertions of a public language sentence meaning *the conflict in the Middle East will not be resolved*. The fear is more likely to give rise to appropriate emotional states.

What Is Mentalese Like?

The Thinker's Public Language, or a Proprietary Inner Code?

Some theorists have supposed that mentalese is just the thinker's own public language. English speakers think in English, Chinese speakers in Chinese. One might be inclined to this view by reflecting on the fact that many thoughts do not seem possible until the thinker has acquired a public language. Consider, for example, the thought that *the leech of the genoa is curled*. A subject cannot genuinely think this thought until she has acquired the concepts *leech* and *genoa*. Moreover, acquiring such concepts seems to require learning the appropriate public language terms for them, or more basic public language terms in which

they can be defined. If mentalese is just the thinker's public language, then investigation of its properties is relatively straightforward. The syntax of an English speaker's mentalese is just English syntax; its semantics is just English semantics.

Jerry Fodor, in his groundbreaking 1975 book, *The language of thought*, argued that thought takes place in a proprietary inner code; moreover, this inner language has the expressive power of any public language a thinker is capable of learning. According to Fodor, the process of language learning involves hypothesis formation and testing; in particular, the hypotheses have the form of 'truth rules' for the application of the public language terms. To learn the English term 'genoa' is to learn a rule of the form "x is a genoa' is true if and only if x is P," where P is a predicate in the proprietary inner language that is coextensive with the English predicate 'genoa.' To learn a public language is to acquire a translation manual that pairs terms in the language of thought with their public language equivalents. On pain of regress, terms in the language of thought are not themselves learned. A consequence of Fodor's view is that the concept *genoa* – and *electron*, *carburetor*, and any other concept a thinker can possess – is either innate or definable in terms of other concepts that are themselves innate. Fodor argues (Fodor, 1981) that few concepts are so definable; hence the vast majority of a thinker's concepts are innate.

Needless to say, many have found Fodor's extreme nativism unpalatable. His argument depends upon construing (public) language learning as hypothesis formation and confirmation, a process that requires an internal medium of representation, a language of thought where the hypotheses are couched. But there is nothing inevitable about explicit hypothesis formation and testing models of learning. If public language predicates were learned as a result of a causal process that is not construed as linguistic or inferential – a process sometimes known as 'triggering' – then the argument's nativist conclusion would not follow.

Whatever their views on concept-nativism, most proponents of the view that thought takes place in a linguistic medium have followed Fodor in claiming that the language of thought is an inner neural code, distinct from any public language. Accordingly, we will hereinafter construe the 'language of thought hypothesis' (LOT) as the view that thought takes place in a proprietary inner code.

Psycho-Syntax and Psycho-Semantics

If the language of thought is indeed an inner neural code, then discovering its syntax and semantics will require extensive empirical investigation of the mind. Characterizing the syntax of mentalese will involve a

specification of a finite set of primitive objects (words), and a grammar or set of formation rules that describe the ways in which complex syntactic objects (sentences) may be built out of the primitives. The individuation of syntactic types will be functionally based, adverting to the causal roles of these objects in the subject's cognitive life.

The so-called 'mental logic' research program that attempts to uncover the formal rules of inference underlying human deductive reasoning presupposes the existence of an innate syntax of thought and proposes to empirically investigate it. (See the papers in Braine and O'Brien, 1998.) Various candidate inference schemas have been offered, but no proposal is sufficiently detailed to generate empirically testable predictions regarding the underlying syntax.

A full theory of mentalese also requires a 'psycho-semantics' – an account of how internal sentences acquire their meaning. In virtue of what fact does a particular mental sentence mean *snow is white* rather than $2+2=4$? The meanings of public language sentences are fixed by public agreement, or derive in some way from the mental states of the users of these sentences, but, on pain of circularity, the sentences of mentalese must acquire their meanings in some other way. Since the 1980s, there has been a proliferation of theories, mostly by philosophers, purporting to explain how mental representation is possible. Not all of these accounts presuppose LOT, but most, if not all, are compatible with it. Typically, such theories attempt to explain the semantic properties of thought while respecting a naturalistic constraint – they attempt to specify sufficient conditions for a mental state's meaning, what it does in nonsemantic and nonintentional terms. (See Stich and Warfield, 1994 and *Representation in Language and Mind*.)

Further Arguments for LOT

Theories of Mental Processing Are Committed to LOT

Fodor (1975) reasoned that the only plausible models of mental processing are computational models, and that these require a medium of computation, that is, an inner system of representation. This argument has now been undermined by the existence of connectionist computational models. Connectionist machines are capable of performing cognitive tasks, but they lack fixed symbols over which computational operations are defined. Connectionist processes are not naturally interpretable as manipulations of internal sentences or data structures. If the mind is best characterized as a connectionist machine, or as an aggregate of such machines without an overarching executive control, then the LOT hypothesis is false.

LOT Explains Some Pervasive Features of Thought

Fodor (1987) argues that LOT provides the best, indeed, the only explanation of two pervasive features of thought. Thought is **productive**: we can think arbitrarily many thoughts. It is also **systematic**; cognitive capacities are systematically related. If a subject can think the thought *John loves Mary*, then he can think the thought *Mary loves John*. The explanation for the productivity and systematicity of thought is that thoughts have a language-like structure. We can think arbitrarily many thoughts for the same reason that we can utter arbitrarily many sentences. Thoughts, like sentences, are composed of a finite base of elements put together in regular ways, according to the rules of a grammar. The systematicity of thought is also explained by LOT: systematically related thoughts contain the same basic elements but are arranged differently.

Whether the argument is successful depends on two issues: (1) whether productivity and systematicity are indeed pervasive features of thought; and (2) if they are, whether they can be accounted for without positing a language of thought.

Thoughts are assumed to be productive because they are represented, described, and attributed by public language sentences, a system which is itself productive. However, as noted above, one must be careful not to attribute to thoughts themselves properties of the representational scheme that we use to talk about them. It would be a mistake to think that temperature is infinite because the scheme used to measure it, the natural numbers, is infinite. If thoughts are understood as internal states of subjects that are, typically, effects of external conditions and causes of behavior, then it is not obvious that there are arbitrarily many of them. The size of the set of possible belief-states of human thinkers, like the size of the set of possible temperatures of objects, is a matter to be settled by empirical investigation.

Turning to systematicity, the argument falls short of establishing the existence of mentalese. In the first

place, it is not clear how pervasive systematicity really is. It is not generally true that if a thinker can entertain a proposition of the form aRb , then she can entertain bRa . One can think the thought *the boy parsed the sentence*, but not *the sentence parsed the boy*. Moreover, it is a matter of some dispute within the cognitive science community whether connectionist cognitive models, which do not posit a language of thought, might be capable of explaining the systematic relations that do hold among thoughts. (See MacDonald and MacDonald, 1995 for the classic papers on this issue, and Matthews, 1997 for further discussion).

Metalanguage versus Object Language

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Human languages are the objects studied in linguistics. For that reason, the language under investigation is known as the object language. The language that a linguist uses to describe and analyze the object

language is called the metalanguage. The basic requirement for a metalanguage is that it satisfactorily communicates the form, structure, and meaning of item e_{OL} – that is, any expression in the object language, whether it is a word, a phrase, or a sentence – in terms of an expression ' e_M ' in the metalanguage. This short article focuses on semantic metalanguages.

Ideally, a metalanguage is a formal language, as in (2); (1) is informal.

- (1) *dog* means ‘canine animal’
 (2) $\forall x[D(x) \leftrightarrow \lambda[A(y) \wedge C(y)](x)]$

Dog is e_{OL} and ‘canine animal’ is ‘ e_M ’; note the typographical differentiation. Example (2) makes recourse to natural language vocabulary because the *D*, *A*, and *C* symbolize *dog*, *animal*, and *canine*; (2) can be read ‘Everything that is a dog is a member of the set of individuals that are both animal and canine’. Strictly, a formal language has a fully defined vocabulary and syntax. Ideally, the vocabulary is a specified set of symbols whose forms and correlated meanings are fully defined, all possible combinations of vocabulary items in the metalanguage are generated from fully specified syntactic axioms and rules of syntax, and the meanings of syntactically well-formed structures are fully specified by semantic axioms and rules for the metalanguage.

A metalanguage is, in effect, a translation of the object language (Carnap, 1937: 228); so, defining a formal metalanguage for natural language semantics requires that it have the same expressive power as a natural language. In order for the metalanguage to be understood and used by human beings, it must be communicable and, hence, translate into a natural language. If you understand neither Polish nor Swahili, there is little point in my using Swahili as a metalanguage for the semantic analysis of Polish (or vice versa); for example, my saying that *to jest pies* means ‘ni mbwa’ will not help you at all. Using English as a metalanguage, I would say *to jest pies* means ‘it’s a dog’; using English as a metalanguage, I would say *to jest pies* means ‘ni mbwa’ (in Swahili), which means ‘it’s a dog.’

The advantages of a formal metalanguage are the explicit definition of primitives and standards of rigor and exactitude that tend to be ignored when using an informal metalanguage. The proper formalization of the metalanguage permits proofs of particular conclusions about semantic structure and so prevents mistaken conclusions deriving from faulty assumptions and/or inference procedures. However, none of these advantages of a formal system is necessarily unobtainable using an informal system such as a natural language metalanguage for semantics. Given two metalanguages with the same descriptive and explanatory capacities, the only way to choose between them is to be guided by gut feeling: favor the one you are happier with. A metalanguage is the product of an analyst’s mind; the analyst not being God, every metalanguage is limited by the beliefs, perspectives, and purposes of its creator.

Metaphor: Philosophical Theories

M Arseneault, University of Wisconsin-Madison, Madison, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

Metaphor and Philosophy

Rather than simply interpreting particular metaphorical expressions, philosophers of language investigate questions such as whether metaphors mean what they do in virtue of semantic content, or whether pragmatic features of expression use and context determine the meaning of metaphors. Answering such questions requires addressing fundamental issues in language

and communication such as issues about the limits of literal meaning and the semantic-pragmatic distinction.

Defining Metaphor

Metaphor theorists disagree about which class of expressions constitutes the proper object of an analysis of metaphor. While most metaphor theorists favor live metaphors (metaphors that invite a multitude of interpretations), others such as George Lakoff and Mark Johnson (1980) focus on dead metaphors (metaphors with a relatively fixed meaning) and their role in structuring cognition. At the same time, some metaphor

theorists adopt broader definitions while others work with narrower definitions of metaphor.

Metaphor, in its broadest sense (metaphor₁), includes most if not all figurative language such that the principle contrast is between metaphorical and literal language. Narrower definitions take metaphor to be only one among many other non-literal tropes. A second type of metaphor (metaphor₂), distinct from other non-literal tropes such as irony, metonymy, and synecdoche, is what makes us think of one thing *as* another. Since the very possibility of giving a unified account of metaphor₁ is remote, articulating an account of metaphor₂ is a more appropriate goal. However, a demarcation problem remains a challenge for any treatment of metaphor₂: it must be worked out what it means to say that metaphor₂ makes us think of one thing as another in such a way that the difference between metaphor and other non-literal tropes is illuminated.

Delineating Metaphor

The class of metaphorical expressions can be delineated by form or by function. The paradigmatic form of metaphors is the subject-predicate form *S is P*. Metaphorical expressions of this kind are the focus of, for example, John R. Searle's (1993) account of metaphor. According to Searle, a speaker utters an expression of the form *S is P* (*Juliet is the sun*) in order to convey an intended proposition (that Juliet is radiant) of the form *S is R*.

Other accounts of metaphor delineate the class of metaphorical expressions according to a specific understanding of metaphor's function to make us think of one thing as another. For example, the comparison view of metaphor is the view that metaphor functions by comparing two things (Juliet and the sun). Delineating metaphor according to this function assimilates simile to the class of metaphors.

The clear disadvantage of constructing an account of metaphor around any particular form, even paradigmatic forms, is that doing so leaves unexplained other expression forms that have a plausible claim to metaphoricity. Extended metaphors that run the length of a poem and noun-function metaphors of the form *The B of A* (*The countless gold of a merry heart*) are not easily captured by the form *S is P*. Since diverse forms can carry out the same function, functional definitions of metaphor do better at capturing non-paradigmatic forms. Functional definitions explain why we use metaphor (e.g., to compare) in a way that form alone cannot.

The Metaphorical and the Literal

Almost every metaphor theorist accepts the Deviance Thesis: metaphor is essentially nonstandard and

deviates either semantically or pragmatically from ordinary literal language. The Deviance Thesis is reflected in the persistent, but challenged (Cohen, 1976), view that metaphors are either literally false or conceptually incongruous.

Deviance and Value

Historically, the deviance of metaphor has been tied to the question of the value of metaphor. Although Cicero (*De Oratore*), Quintilian (*Institutio Oratoria*), and rhetoricians celebrated the deviance of metaphor and its embellishment of language, philosophers John Locke (*Essay concerning human understanding*) and Thomas Hobbes (*Leviathan*) condemned the use of metaphor in philosophical inquiry. If the best chance at arriving at and communicating truth is afforded only by unambiguous literal language use, metaphor's deviance from the literal is therefore suspect. Jean-Jacques Rousseau (*Essay on the origin of languages*) and Friedrich Nietzsche (*On truth and falsity in their ultra-moral sense*) attempted to undercut this criticism by arguing that all language is fundamentally metaphorical and championed metaphor's creative function. For a short history of philosophical thought about metaphor, see Johnson (1981) and Kittay (1987).

Deviance: Semantic or Pragmatic?

The cognitive value of metaphor is now generally conceded and metaphor's deviance is considered separately from its value. Contemporary accounts of metaphor characterize its deviance either as a violation of semantic rules or as a violation of pragmatic constraints. Various semantic theories can describe the semantic deviance of metaphor; for example, it can be described as a violation of selection restrictions or as a violation of standard meaning lines between possible worlds. Samuel R. Levin (1977) describes construal mechanisms for assigning interpretations to anomalous or deviant sentences, including the metaphors of ordinary language use and conversation. Metaphors are semantically deviant because they fall outside the class of sentences generated by normal operation of the rules of grammar. According to the metaphor *The stone died*, to be a stone in the metaphoric sense (to be a dunce) is to be similar in characteristics to a stone in the literal sense. The noun *stone* has semantic markers that might include (((Object) (Physical)) (Nonliving) (Mineral))), and the verb *die* has semantic markers that may include ((Process) ((Result) ((Cease to be) (Living)))). The verb has selection restrictions ((Human) or (Animal) or (Plant)), and it is these restrictions that are violated in *The stone died*. Construal rules that sanction the transfer of the feature (Human) to the semantic markers of *stone*, for example, allow us to derive the interpretation that the dunce died.

Jaakko Hintikka and Gabriel Sandu (1990) characterize the semantic deviance of metaphor according to possible world semantics. On this view, meanings are functions from possible worlds to classes of individuals. We can visualize this function by imagining that a notional meaning line connects the individuals, in their respective possible worlds, picked out by the function. Metaphoric meaning is a function that draws nonstandard or deviant meaning lines: they differ from literal meaning lines in that they rely exceptionally heavily in some specific respect on either qualitative or functional similarity. In *The stone died*, the speaker draws the meaning lines of *stone* on the basis of qualitative hardness and immovability.

Pragmatic accounts of metaphor are motivated by the observation that the very same expression (for example, *A storm is gathering*) can be interpreted literally in one context (said of a dark and windy sky) and yet be intended and interpreted metaphorically in another context (said of an anticipated faculty meeting). A full explanation of metaphor, then, must look beyond merely the expression itself to the context of the utterance. H. Paul Grice's theory of conversational implicature provides a pragmatic account of the deviance of metaphor. Conversational implicatures, including metaphor, arise when what is said violates conversational maxims. Grice (1975) says that metaphor violates the conversational maxim of saying only what is true, while Dan Sperber and Deirdre Wilson (1986) argue that it violates the principle of saying only what is relevant. In either case, it is noticing that what is said deviates from these maxims and principles that prompts the hearer to search for an interpretation of the utterance (*Juliet is the sun*) such that the speaker is contributing something true or relevant to the conversation (that Juliet chases away darkness).

Joseph Stern (2000) presents a dual challenge to the Deviance Thesis: unlike Levin, Stern argues that metaphor is not grammatically deviant and, in contrast to Gricean pragmatic accounts, that it is not necessary to first notice that what is said is deviant. Stern suggests that metaphor is a linguistic type representable in the grammar by the operator *Mthat*[Φ]. Like indexicals and demonstratives, metaphors have both a character and a content. The character, or meaning, of a metaphor is the linguistic function from context to content expressions; the content of a metaphor is the propositional content determined by the character (i.e., the interpretation of the metaphorical expression). For example, in an analysis of *Juliet is the sun*, in which the predicate is the metaphorical component, the character of the metaphor picks out the content of {*Mthat*['is the sun']}, that is, properties (nourishing, chasing away darkness, etc.) that are associated with the sun.

Stern argues that metaphor is not pragmatically deviant in the way suggested by implicature theorists, insofar as what is conveyed by a metaphor is not inferentially derived against a background of conversational maxims. Instead, the rules of grammar simultaneously make available metaphorical and literal interpretations. Stern and others (Glucksberg and Keysar, 1993; Récanati, 1995) cite evidence that the metaphorical interpretation of the sentence is processed in parallel with, and not serially to, the literal interpretation. It is not necessary to recognize first that what is said violates pragmatic constraints.

Theories of Metaphor

Conditions of Adequacy

Theories of metaphor are successful to the extent that they fulfill certain conditions of adequacy. For example, the proposal that metaphorical expressions are ambiguous fails, because it cannot explain how the meaning of the metaphorical expression depends on the literal meaning of the words used. Unlike ambiguous expressions (example, *bank*), the meaning of the words on one (literal) interpretation stay 'active' and guide the other (metaphorical) interpretation. Other desiderata include explanations of the expressive power and catachretic function of metaphor to remedy gaps in the vocabulary by using words in new ways. Accounts should make sense of the ubiquity of metaphor and explain why some metaphors fail. The more controversial features of metaphor, such as its apparent falsity and nonparaphrasability, must either be accounted for or be explained away. For further discussion of these and other conditions of adequacy, see Nogales (1999).

Aristotle

Aristotle defines metaphor as the transference of a name from genus to species, from species to genus, from species to species, or by analogy. In his influential treatment of metaphor (found in *Poetics* and in *Rhetoric*) we find the seeds of substitution, analogy, and simile theories of metaphor. Under Quintilian's substitution theory of metaphor, a new decorative name is transferred to an object in substitution for its usual plain name, though for merely rhetorical effect. Analogy theories of metaphor have been of particular interest to those interested in the predictive nature of scientific models (Hesse, 1966; Gentner, 1982). Because Aristotle thinks that the function of both simile and metaphor trades on comparison and noticing pre-existing similarities, he is also credited as an early proponent of the view that metaphor is a kind of simile. The elliptical simile theory of metaphor

specifies that metaphors such as *Time is a child at play* are ellipses of corresponding similes (*Time is like a child at play*). Lynne Tirrell (1991) argues that not all metaphors have corresponding similes, such as metaphors of the form *A is Ψ* (*The moon is envious*). Therefore, although metaphor theorists continue to be tempted to explain metaphor in terms of simile (Fogelin, 1988), elliptical simile theories of metaphor apparently cannot serve as general theories of metaphor.

Interaction Theories of Metaphor

Interaction theories of metaphor have a prominent place among contemporary semantic theories of metaphor. Introduced by I. A. Richards (1936) and Max Black (1962), this kind of theory proposes that instead of simply re-naming or comparing objects, two concepts or systems of associated commonplaces are simultaneously 'interactive.' In *my love is a rose*, the source (also called 'vehicle' or 'focus') *rose* projects an isomorphic set of connotations or believed commonplaces (such as fragility) upon the topic (also called 'tenor') *my love*. Eva Feder Kittay (1987) articulates this interaction in terms of semantic field theory. In this theory, the meaning of a term is a function of its relation (of affinity or contrast) to the other terms in its semantic or conceptual field. For example, the meaning of *midwife* is a function of its semantic field structured according to relations among the agent (midwife), her patient (the mother), and the result (the child). For Socrates's metaphor of teachers as midwives, interactive projection consists of restructuring the relations among the terms in topic field (*teacher*) analogously to those in the source field (*midwife*). Reconceiving the topic in this manner permits the special and controversial creativity of metaphor: metaphor goes beyond exploiting existing similarities to create new similarities or perspectives on the world (perspectival theory of metaphor). Metaphor makes us think of one thing as another because its function is to create a perspective from which we gain an understanding of that which is metaphorically portrayed.

Davidson and Metaphorical Meaning

Donald Davidson (1978) gives what is perhaps the most influential objection to any semantic treatment of metaphor. According to Davidson, the fundamental error of all semantic accounts of metaphor is to read the contents of the thoughts provoked by the metaphor into the content of the expression itself. Davidson denies that the concept of metaphorical meaning is required to explain how metaphor achieves its effect. Sharply distinguishing between what words

mean and what words are used to do, Davidson argues that it is the meaning of words that is supposed to explain what can be done with words (and not, for example, the effects achieved by metaphor that explain the meaning of the metaphorical expression). It is because literal meaning and truth conditions, but not metaphorical meaning, can be assigned to sentences apart from particular contexts of use that only literal meaning has genuine explanatory power. If there is no metaphorical meaning, then theories of metaphor can tell us about the effects metaphors have on us, but they do not provide a method for decoding a special content conveyed by the metaphorical expression. See Leddy (1983) and Farrell (1987) for criticisms of Davidson's view, and Crosthwaite (1985) for a defense of Davidson's account.

Metaphor: Psychological Aspects

R Gibbs, University of California, Santa Cruz, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The psychological study of metaphor has had a major impact on the interdisciplinary understanding of language and thought. Thirty years ago, the topic of metaphor was mostly seen as peripheral to the major focus of research in both linguistics and psychology, because metaphor was primarily viewed as a poetic device that is not representative of how people ordinarily speak or think. But in conjunction with the emergence of cognitive linguistics in the 1970s and 1980s, psychological research has demonstrated that metaphor is ubiquitous in discourse, can often be easily understood and produced in appropriate social and linguistic contexts, and perhaps most importantly, is both a type of language use and a fundamental scheme of thought. This entry describes the empirical evidence relevant for, and the theories building on, these claims.

The Ubiquity of Metaphor in Language

Metaphor has traditionally been viewed as a distortion of both thought and language, because it involves the transfer of a name to some object to which that name does not properly belong. Speakers and writers presumably use metaphor as an ornamental feature for poetic and rhetorical purposes (e.g., to say what is difficult to state literally, to express meaning in a vivid manner), rather than to impart fundamental

concepts. In each case of metaphorical language, a person aims to present some underlying analogy or similarity in the form of a condensed or elliptical simile. Thus, a metaphor of the 'A is B' form indirectly implies the speaker's intended literal meaning "A is like B in certain respects." For instance, the metaphor 'The car beetles along the road' describes the movement of the car as being like the movement of a beetle. Under this traditional view, metaphor should be infrequent in language, especially in scientific discourse, and people should have more cognitive difficulty when uttering and understanding metaphors than they do when using the equivalent literal speech.

Psychological research has shown, however, that metaphor is a major part of both spoken and written language. Various studies have attempted to quantify the frequency of metaphor use in a variety of contexts. One detailed study examined the use of metaphor in transcripts of psychotherapeutic interviews, in various essays, and in the 1960 Kennedy-Nixon presidential debates and found that people used 1.80 novel and 4.08 frozen metaphors per minute of discourse (Pollio *et al.*, 1977). If one assumes that people engage in conversation for as little as 2 hours per day, a person would utter 4.7 million novel and 21.4 million frozen metaphors over a 60-year life span! A different analysis of the metaphors produced in television debates and news commentary programs showed that speakers use one unique metaphor for every 25 words (Graesser *et al.*, 1989). These, admittedly crude, analyses clearly demonstrate that metaphor is not the special privilege of a few gifted

speakers, but is ubiquitous throughout both written and spoken discourse.

However, a closer look at everyday language suggests that these empirical attempts to 'count' instances of metaphor vastly underestimate the pervasiveness of metaphor in people's ordinary speech. Typical frequency counts of metaphor do not include analysis of conventional speech that is motivated by metaphoric modes of thought. Consider the following mundane expressions that people often use in talking about verbal arguments (Lakoff and Johnson, 1980).

Your claims are indefensible.
I've never won an argument with him.
I demolished his argument.
He attacked every weak point in my argument.
His criticisms were right on target.
He shot down all of my arguments.

At first glance, none of these expressions appear to be very metaphoric, at least in the same way that an utterances such as 'The sun is the eye of heaven' might be. Yet, a closer look reveals the systematic metaphoric structuring whereby people think of arguments in terms of wars. We can actually win or lose arguments. We see the person we are arguing with as an opponent. We attack his positions, and we defend our own. We plan and use strategies. We might find certain positions undefensible, requiring us to take new lines of attack. Each of these things do not simply reflect the way we talk about arguments: we actually argue as if we were in a war. Our understanding of argument as war is active and widespread, but this concept is so deeply entrenched in our ordinary conceptual system that we tend to miss its metaphorical character.

Cognitive linguistic research has suggested that there are perhaps hundreds of conceptual metaphors, such as ARGUMENTS ARE WARS, that structure our everyday experience, and that they are found in a wide variety of conceptual domains (Gibbs and Steen, 1999; Kövecses, 2002; Lakoff and Johnson, 1999). Linguistic analyses do not typically quantify the number of verbal metaphors, and the conceptual metaphors underlying them, that may be present in any one sample of speech or text. But one psychological study of the narratives women produced when describing their experiences recovering from cancer showed that conventional metaphoric language was employed more than 6 times per minute, and that only 22 conceptual metaphors underlay the vastly different metaphoric expressions these women produced, especially in their talk of emotion (Gibbs and Franks, 2002). Conceptual metaphors seem to be ubiquitous in the ways people talk of their experiences.

One question that has generated a great deal of debate within psychology is whether these instances of conventional metaphor necessarily reflect anything about the metaphorical nature of many abstract concepts.

Metaphor Understanding: The Standard View

The traditional belief that metaphor is deviant suggests that metaphors should be more difficult to interpret than literal speech. The most famous proposal along this line comes from H. Paul Grice's theory of conversational implicature (Grice, 1989) (also see Grice, H. Paul (1913–1988); *see* **Implicature**). Grice argued that the inferences needed to understand nonliteral meaning are derived from certain general principles or maxims of conversation that participants in talk-exchange are mutually expected to observe (Grice, 1989) (*see* **Maxims and Flouting**). Among these are expectations that speakers are to be informative, truthful, relevant, and clear in what they say. When an utterance appears to violate any of these maxims, as in the case of metaphor, listeners are expected to derive an appropriate 'conversational implicature' about what the speaker intended to communicate in context, given the assumption that he or she is trying to be cooperative (*see* **Cooperative Principle**).

Grice (1989) more specifically suggested what has become known as the 'standard pragmatic model' for understanding indirect and nonliteral meanings, including metaphor. In this view, understanding metaphor is accomplished in a series of steps: (1) analyze the literal meaning of an entire expression, (2) compare this literal meaning to the context, (3) if the literal meaning is appropriate, then stop, otherwise (4) derive an alternative meaning that makes the speaker's/writer's utterance sensible in the context, given the cooperative principle. This rational account suggests, then, that metaphors are understood as conversational implicatures and should take additional time to comprehend over that needed to interpret literal speech that is appropriate to the context.

Psychological Tests of the Standard View

How accurate is the standard view as a psychological theory of metaphor understanding? First, the results of many reading-time experiments in psycholinguistics show that people do not always require additional mental effort to comprehend many kinds of figurative utterances, as compared with so-called literal speech (Gibbs, 1994, 2002). Listeners/readers often take no longer to understand the figurative

interpretations of metaphor (e.g., 'billboards are warts on the landscape'), metonymy (e.g., 'The ham sandwich left without paying'), sarcasm (e.g., 'You are a fine friend'), idioms (e.g., 'John popped the question to Mary'), proverbs (e.g., 'The early bird catches the worm'), and indirect speech acts (e.g., 'Would you mind lending me five dollars?') than to understand equivalent literal expressions, particularly if these are seen in realistic linguistic and social contexts. Appropriate contextual information provides a pragmatic framework for people to understand metaphoric utterances without any recognition that these utterances violate conversational norms. In fact, psychological studies have specifically shown that people do not need to find a defective literal meaning before searching for a nonliteral meaning. For example, people apprehend the metaphoric meanings of simple comparison statements (e.g., 'surgeons are butchers') even when the literal meanings of these statements fit perfectly with the context (Glucksberg *et al.*, 1982). Even without a defective literal meaning to trigger a search for an alternative meaning, metaphor can be automatically interpreted.

These experimental findings from psycholinguistics are damaging to the general assumption that people understand metaphor as violations of conversational maxims. Similar psychological mechanisms appear to drive the understanding of both literal and metaphoric speech, at least insofar as early cognitive processes are concerned. Everyone agrees that people may sometimes take a good deal of time to process novel poetic metaphors, for example. Studies have shown, in fact, that conventional, or familiar, metaphors can be understood more quickly than novel expressions (Katz and Ferretti, 2001). Yet the additional time needed to understand novel metaphors is not necessarily due to a preliminary stage during which the literal meaning for an entire utterance is first analyzed and then rejected. Listeners may take longer to understand a novel expression, such as 'The night sky was filled with molten silver,' because of the difficulty in integrating the figurative meaning with the context, and not because listeners are first analyzing and then rejecting the expression's literal meaning (Schraw, 1995).

Many psychologists have gone on to argue that even if metaphor does not necessarily demand extra cognitive effort to understand, people may still analyze literal, conventional, or salient, aspects of word meaning during immediate metaphor comprehension (Blasko and Connine, 1993; Giora, 2001). Some studies, which measure the meanings activated during each part of the moment-by-moment process of linguistic understanding, suggest that comprehending familiar and novel metaphors engages different

linguistic processes. Analysis of literal word meaning still precedes metaphorical meaning during novel metaphor understanding, with both types of meaning arising in parallel during familiar metaphor processing. Other studies that assessed people's speeded judgments about the sensibility of different word strings at different moments find no difference in the comprehension speed for literal and figurative strings (McElree and Nordlie, 1999). This lack of time-course differences is inconsistent with the claim that metaphoric interpretations are computed after a literal meaning has been analyzed, and suggest that literal and metaphoric interpretations are computed in parallel.

Although these research findings imply that metaphor processing is not secondary to literal understanding, psycholinguists are, again, careful to note that people may be biased toward initially interpreting the literal, or salient, meanings of metaphoric statements in cases of novel metaphor (Giora, 2001). Yet others argue that even if some linguistic meanings (e.g., literal or metaphoric) are created sooner during metaphor processing, these findings do not imply that entirely different mental processes operate to produce these different meanings (Gibbs, 2002). Different kinds of meaning may arise from a single linguistic process. The fact that scholars label one kind of meaning 'literal' and another 'metaphoric' doesn't necessarily indicate that different processes operate (such as a literal processing mode and a metaphoric processing mode) as people access these meanings (either in a serial or parallel manner).

More recent theories of figurative language understanding, which are more general than metaphor theories *per se*, suggest that people may initially access a word's interpretation that can be compatible with both its literal and metaphoric meanings (Frisson and Pickering, 2001). Over time, however, people use context to home in on the word's appropriate metaphoric meaning, where the homing-in process is faster when the preceding context is strong, and slower when the preceding context is neutral. In this way, context does not operate to distinguish between different literal and metaphoric meanings, as assumed by most theories (such as in the standard model), but functions to change an underspecified, or highly general meaning, into a contextually appropriate, specific interpretation which may be metaphorical.

A different theory embraces the notion of 'constraint satisfaction' to provide a comprehensive model of the different sources of information that constrain metaphor understanding (Katz and Ferretti, 2001). Under this view, understanding a metaphoric utterance requires people to consider different linguistic (e.g., people's familiarity with words and phrases) and nonlinguistic (e.g., related to specific

context) information that best fits together to make sense of what a speaker or writer is saying. These different sources of information are probabilistically evaluated, and combined to offer a most likely 'winning' meaning for a metaphor. A constraint satisfaction model may have the flexibility to account for a wide variety of metaphor processing data that seems to differ depending on the familiarity or conventionality of the expression, the context in which it is encountered, and the speaker's/writer's likely intentions in using metaphorical language.

In summary, there has been a great deal of psychological research devoted to the general question of whether metaphorical language requires additional cognitive effort to understand, compared to non-metaphorical speech. The findings of these widely varying studies strongly imply that metaphors are not deviant and do not necessarily take more time to understand, but that more subtle factors, such as the familiarity of the expression and the context in which it is used, can shape the time-course of metaphor understanding. Many studies now situate metaphor understanding within a more comprehensive view of linguistic processing that does not posit specialized mechanisms for interpreting metaphors, even if these expressions often convey distinctive kinds of meanings (Kintsch and Bowles, 2002), and which specifically relies on cognitive mechanisms, such as suppression, that are employed widely in all aspects of language processing (Gernsbacher and Robertson, 1999).

Psychological Models of Metaphor Understanding

A great deal of research has been devoted to the specific processes involved in understanding metaphorical meaning, beyond the general question of whether metaphors are more difficult to comprehend than literal speech. These studies have explicitly examined the ways that the A, or target, and B, or vehicle, terms interact to produce metaphorical meaning. A long-standing assumption in many academic fields is that we understand metaphors by recognizing the ways that topic and vehicle terms are similar. Thus, in understanding the metaphor 'Juliet is the sun,' listeners are presumed to figure out the properties of both Juliet and the sun that are similar.

But psychological studies indicate that metaphor comprehension does not demand that the topic and vehicle terms share properties or associations (Camac and Glucksberg, 1984). This finding is supported by many studies showing that metaphors have directional meaning. If metaphorical meaning arises from the overlap of the semantic features of topic and vehicle, expressions such as 'The surgeon is a butcher' and

'The butcher is a surgeon' should have similar metaphorical meanings. But this is clearly not the case. The similarity that arises from the comparison of a topic and vehicle does not produce metaphorical meaning. Instead, similarity is created as an emergent property of understanding metaphor. Thus, many psychological studies have demonstrated that novel features emerge from metaphor comprehension that are not salient in one's separate understanding of the topic or vehicle (Gineste *et al.*, 2000). This idea is consistent with the popular, but somewhat vague, interactionist theory of metaphor (Black, 1979), which argues that the presence of the topic stimulates a listener to select one of the vehicle's properties so as to construct a 'parallel implication complex' that may induce changes in one's understanding of both the topic and vehicle. In general, psychological studies provide strong evidence supporting the idea that metaphor cannot be reduced to rule-governed extensions or variations of the topic's and vehicle's literal meanings.

Psychologists disagree, however, about the cognitive mechanisms involved in feature emergence during metaphor understanding. The two main proposals state that metaphorical mappings between concepts from dissimilar domains can be accomplished by either comparison or categorization processes. Traditional comparison theories posit that metaphor understanding demands a mapping of low-salient features from the source domain with high-salient features of the target domain (Miller, 1979). But understanding many metaphors, such as 'Men are wolves,' seems to involve the activation of semantic features that are not typically associated with either the source or target domain until after the metaphor has been understood (Ortony, 1979). Gentner's 'structure-mapping' theory of analogy and metaphor avoids this problem by suggesting that people begin processing a metaphor by first aligning the representations of the source and target domain concepts (see Gentner *et al.*, 2001). Once these two domains are aligned, further inferences are directionally projected from the source to the target domain. Finally, new inferences arise within the target domain, reflecting relational, and not just feature-specific, aspects of the metaphor comprehension processes. Experimental evidence in support of this comparison view shows, for instance, that people infer relational, but not feature-specific, meanings when interpreting metaphors (Gentner *et al.*, 2001). For instance, when people read 'Plant stems are drinking straws,' they infer that both plants and straws convey liquid to nourish living things, and not just that both plants and straws are long and thin (i.e., object commonalities). Other research indicated that metaphors that express relational information (e.g., 'Plant stems are drinking straws')

are viewed as being far more apt than those that only map object features ('Her arms were like twin swans').

An alternative view claims that metaphors are better understood via categorization processes, as class-inclusion, rather than comparison, statements (Glucksberg, 2001). For example, the statement 'Yeltsin was a walking time bomb' asserts that the former Russian President is a member of a category that is best exemplified by time bombs. Of course, time bombs can belong to several other categories, such as the weapons used by terrorists. But in the context of talking about people, time bombs best exemplify the abstract category of 'things that explode at some unpredictable time in the future and cause a lot of damage.' In this way, metaphors reflect *ad hoc* categories and refer at two levels: the concrete level (i.e., an explosive device) and a superordinate level (i.e., the properties of time bombs).

One implication of the class-inclusion model is that it suggests that the topics and vehicles, or target and source domains, in metaphors play different but interactive roles in metaphor comprehension. For example, the word 'snake' evokes different meanings in the phrases 'my lawyer is a snake' and 'the road was a snake.' In this way, metaphor topics provide dimensions for attribution, while vehicles provide properties to be attributed to the topic. Psychological evidence supporting this position showed that in a reading-time study, presenting people first with a topic term that is highly constrained reduces the time needed for the subsequent processing of a metaphorical statement, in contrast to when people are first presented with a less-constrained topic (Glucksberg, 2001). Furthermore, presenting people with an unambiguous vehicle primes subsequent metaphor comprehension, in contrast to what happens when they are presented with an ambiguous vehicle term. This pattern of data illustrates how the level of constraint is an important feature of metaphor topics, while the degree of ambiguity is an important characteristic of metaphor vehicles. Comparison models of metaphor understanding are unable to explain the importance of constraint and ambiguity, because they assume that metaphor comprehension always begins with an exhaustive extraction of the properties associated with both topics and vehicles. Having advance knowledge about either the topic or vehicle should presumably, then, prime metaphor processing. However, the categorization view correctly predicts that only advanced knowledge about highly constrained topics and unambiguous vehicles facilitates metaphor comprehension, a finding that is most consistent with the claim that metaphor understanding involves creating a new, *ad hoc* category and not merely comparing one's knowledge about topic and vehicle domains.

A proposal titled the 'career of metaphor' theory combines aspects of both the comparison and categorization views (Gentner and Bowdle, 2001). This theory claims that there is a shift in the mode of mappings from comparison to categorization processes as metaphors become conventionalized. For instance, novel metaphors such as 'Science is a glacier' involve base terms, such as 'glacier,' with a literal source (i.e., 'a large body of ice spreading outward over a land surface'), but no relational metaphoric sense (i.e., 'anything that progresses slowly but steadily'). People comprehend novel metaphors as comparisons in which the target concept (e.g., 'science') must be structurally aligned with the literal base concept (e.g., 'glacier'). In some instances, the comparison process may lead to the induction of a novel metaphor category. On the other hand, conventional metaphors can be understood either by comparison or categorization processes. For example, the metaphor 'A gene is a blueprint' has two closely related senses (e.g., 'a blue and white photographic print detailing an architect's plans' and 'anything that provides a plan'). The relations between these two senses make the conventional base term polysemous (i.e., semantically related literal and metaphoric meanings). As such, conventional metaphors may be understood by matching the target concept with the literal base concept (a comparison process) or by viewing the target concept as a member of the superordinate metaphoric category named by the base term (a categorization process).

Metaphor in Thought

Most of the psychological research on metaphor has focused on how it is used and understood within language, and has assumed that metaphorical meaning is created *de novo*, and does not reflect preexisting aspects of how people ordinarily conceptualize ideas and events in terms of pervasive metaphorical schemes. But in the past 20 years, various linguists, philosophers, and psychologists have embraced the alternative possibility that metaphor is fundamental to language, thought, and experience. Cognitive linguists, for instance, claim that metaphor is not merely a figure of speech, but is a specific mental and neural mapping that influences a good deal of how people think, reason, and imagine in everyday life (Lakoff and Johnson, 1999). Evidence supporting this claim comes from linguistic research on the historical evolution of what words and expressions mean, the systematicity of conventional expressions within and across languages, novel extensions of conventional metaphors, studies on polysemous word meaning, and nonverbal behaviors such as gesture (Gibbs, 1994; Lakoff and Johnson, 1980, 1999).

However, psychologists have been critical of much of this work and its possible implications for theories about conceptual structure and metaphor understanding. First, most of the evidence for metaphorical thought, or conceptual metaphor, comes from purely linguistic analyses, and psychologists have expressed deep skepticism about these claims on both methodological and theoretical grounds, especially with regard to linguists' heavy reliance on their own linguistic intuitions (Murphy, 1996). Second, some psychologists argue that conceptual metaphor theory is unfalsifiable if the only data in its favor is the systematic grouping of metaphors linked by a common theme (Vervaeke and Kennedy, 1996). Consider again the conceptual metaphor ARGUMENT IS WAR (Lakoff and Johnson, 1980), which presumably motivates conventional expressions such as 'He attacked my argument' and 'He defended his position.' Cognitive linguistic research suggests that any expression about argument that does not fit the WAR theme is usually seen as evidence for another theme, such as WEIGHING, TESTING, or COMPARING. This implies that no linguistic statement can be brought forward as evidence against the ARGUMENT IS WAR metaphor, which makes the basic tenet of conceptual metaphor theory impossible to falsify. Finally, some psychologists argue that many conventional expressions viewed as metaphorical by cognitive linguists are really not metaphorical at all, but are treated by ordinary speakers/listeners as literal speech (Glucksberg, 2001). Simple expressions like 'He was depressed' are entirely literal, and may not be motivated by a conceptual metaphor such as SAD IS DOWN, because they only reflect something about the polysemous nature of meaning (e.g., 'depression' can be used to talk about either physical depression or emotional depression).

Psychological Studies on Conceptual Metaphor

Despite the skeptical reaction of some psychologists to the idea of metaphorical thought, or conceptual metaphor, there is a great deal of psychological evidence supporting the claim that many aspects of people's abstract concepts and reasoning processes are shaped by enduring conceptual metaphor. Studies show, for instance, that conceptual metaphors influence the ways people conceive of various abstract domains, such as emotions, minds, politics, advertising, scientific theories, the self, morality, learning, and problem-solving (Gibbs, 1994; see Steen and Gibbs, forthcoming, for reviews). Most of these studies demonstrate that providing people with a particular metaphorical construal of some domain (e.g., that EMOTIONS ARE

CONTAINERS) can facilitate the way they learn new information, solve problems, and make decisions, if the newly encountered material has a similar metaphorical structure. At the same time, whereas switching from one conceptual metaphor to another may require more cognitive effort in some situations (Langston, 2002), people typically have multiple metaphorical ways of conceiving of most abstract ideas (e.g., THEORIES ARE BUILDINGS, THEORIES ARE FABRIC (Gibbs, 1994). This multiplicity of metaphorical schemes provides another source of evidence for the idea that a good deal of ordinary thought is shaped by metaphor.

Even if people seem able to think metaphorically about various domains, many psychologists and especially many psycholinguists are skeptical about whether conceptual metaphors are normally recruited during people's ordinary comprehension of language (Glucksberg, 2001). These critics find it difficult to believe that conceptual metaphors play much of a role in how people interpret verbal metaphors such as 'Surgeons are butchers' or 'Lawyers are snakes.' To a large extent, the debate over conceptual metaphor settles into two camps: those scholars studying novel metaphors and those studying conventional language that may reflect different conceptual metaphors (e.g., 'He attacked my argument' for ARGUMENTS ARE WARS, 'Our relationship hit a dead end street' for LIFE IS A JOURNEY, and so on). Thus, different approaches to the psychology of metaphor understanding are oriented toward different types of metaphorical language. A likely possibility is that conceptual metaphor may have a strong influence on some aspects of verbal metaphor use, but not on others.

In fact, there is a large body of evidence from psychological studies, employing different methods, that clearly demonstrates that (a) people conceptualize certain topics via metaphor, (b) conceptual metaphors assist people in tacitly understanding why metaphorical words and expressions mean what they do, and (c) people access conceptual metaphors during their immediate, online production and comprehension of conventional and novel metaphors. This work includes studies investigating people's mental imagery for conventional metaphors, as in idioms and proverbs (Gibbs and O'Brien, 1990), people's context-sensitive judgments about the figurative meanings of idioms in context (Nayak and Gibbs, 1990), people's immediate processing of idioms (Gibbs *et al.*, 1997), people's responses to questions about metaphorical expressions about time (Boroditsky and Ramscar, 2002; Gentner *et al.*, 2002), readers' understanding of metaphorical time expressions (McGlone and Harding, 1998), and studies looking at the embodied foundation for conventional metaphoric language (Gibbs *et al.*, 2004).

To briefly give a few examples from these psycholinguistic experiments, studies show that people have a complex metaphorical understanding of many abstract domains, which partially motivates everyday reasoning and language use. For instance, people conceive of the domain of emotions metaphorically, based partly on their embodied experiences of emotions, such that they tacitly know that phrases like 'blow your stack' and 'flip your lid' are motivated by the conceptual metaphor of ANGER IS HEATED FLUID IN A CONTAINER. This metaphorical understanding of anger influences people's judgments about the degree to which someone experiences anger and about the best use of different metaphorical phrases in context (Nayak and Gibbs, 1990). At the same time, people's tacit knowledge of conceptual metaphors constrains the specific mental images they can form for verbal metaphors, and the specific meanings they believe these metaphors express (e.g., that 'blow your stack' means to get very angry while the person is feeling internal pressure, and the expression of the anger is unintentional and forceful) (Gibbs and O'Brien, 1990). In fact, many conventional phrases and idioms, long thought to be dead metaphors, retain much of their metaphorical meaning precisely because they continue to be linked to enduring conceptual metaphors. Finally, priming studies suggest that reading a conventional metaphorical phrase, such as 'John blew his stack,' quickly accesses the conceptual metaphor (ANGER IS HEATED FLUID IN A CONTAINER) that partly motivates why this expression has the particular metaphorical meaning it conveys (Gibbs *et al.*, 1997). Reading another expression with roughly similar metaphoric meaning, such as 'John bit her head off,' activates a different conceptual metaphor (ANGER IS ANIMAL BEHAVIOR), giving rise to the creation of these metaphorical expressions.

The debate over the role that metaphorical thought may play in a psychological theory of verbal metaphor use will likely continue. Once more, it seems inevitable that several of the different approaches to metaphor within linguistics and psychology will become part of a more comprehensive theory of metaphor. Yet it is already evident that the traditional views of metaphor as deviant, ornamental aspects of language and thought no longer are tenable and that psychological studies have provided excellent reasons to believe that metaphor is a fundamental part of the ways people speak and think.

Metaphysics, Substitution *Salva Veritate* and the Slingshot Argument

Metaphysics and Language: Facts, Propositions and 'MCT Operators'

There are lots of examples of metaphysical conclusions being drawn on the basis of linguistic phenomena. Philosophers have tried to prove the metaphysical conclusion that a benevolent all-powerful God exists on the basis of claims about what 'God' means. Others have looked at tense in language and drawn conclusions about the metaphysics of time. This article presents a more technical kind of linguistically based argument, about the metaphysics of facts, propositions and modal/causal/temporal properties – an argument whose claims are especially important in the present context because of their implications for linguistic semantics.

The article is structured as follows. In this section, I first introduce two key metaphysical views: about facts and about factlike propositions. I then introduce, also in this section, some seemingly plausible hypotheses about modality, causation, and temporal order. These are the

metaphysical views which will be attacked on linguistic grounds. In the next section I explain what substitutivity principles are, and survey three different kinds of substitutivity and nonsubstitutivity. Such principles clarify the linguistic phenomena that will be used to attack the metaphysical views. The first two sections essentially introduce crucial background material for the argument. In the third section, I then describe the modest means deployed in attacking the metaphysical targets: the slingshot argument. I end by noting some standard replies to this language-based argument.

I begin with facts. It seems natural enough to think of the world as not being exhausted by the objects in it. That is, to list all the objects in the world is not to say all there is to say about it: one also wants to know what properties the objects have, and what relations they stand in, etc. And to say all that, is seemingly to describe facts. It's also tempting to think that facts consist of complexes of ordinary, everyday objects, properties, relations, etc.; to invent a label, it is tempting to think that facts are 'world bound.' The first view that the slingshot calls into question, however, is precisely that there are such world-bound facts, in the plural. Instead, the argument seeks to show that, if facts are

made up of commonplace worldly things, there can be at most one ‘giant’ one. To be clear about the metaphysical target, it is not the very idea of facts that would have to go, for there are alternative accounts of facts which, at first glance anyway, are not threatened by the slingshot. But those accounts of facts face difficulties of their own – difficulties which world-bound facts, facts as complexes of ordinary things, are not subject to. First, as will emerge below, a rose by any other name would smell as sweet. This suggests that the fact that the rose smells sweet has the rose itself in it, not some way of linguistically describing the rose. Second, part of the point of introducing facts and the like is to see how something distinct from a sentence can serve as the sentence’s meaning, hence, we can’t have every linguistic change in the sentence giving rise to a different fact (or factlike thing). (Strawson, 1950 made this point early on.) Third, we want the same fact (or factlike thing) to give the meaning of sentences in different languages, which again means that a mere change in the word used ought not change the proposition denoted – otherwise ‘It’s raining’ and ‘Está lloviendo’ could end up denoting different things. (I’ll return to this at the end of the article.) All of these points suggest that facts are world bound. But, as we shall see, reflection upon language – and especially upon substitutivity principles – makes it hard to see how they could be.

This takes us to a related point. Positing facts often goes along with the idea that factlike things can serve as the denotations of sentences. For instance, ‘Ottawa is the capital of Canada’ might be taken to stand for something like the fact that Ottawa is the capital of Canada. And ‘Abe Lincoln was assassinated’ might be taken to denote the fact that Abe Lincoln was assassinated. Of course, it can’t really be facts *per se* that are sentence denotations, because false sentences are meaningful, and they cannot stand for facts. (For example, what fact could ‘Toronto is the capital of Canada’ stand for, given that Toronto is not the capital? There simply is no such fact.) Still, something factlike might do the trick: sentence denotations could be taken to be propositions. But the slingshot argument, in attacking facts in the plural, equally calls into question the idea that sentences stand for factlike things: if the argument succeeds, there are no such things, facts or propositions, in the plural, that sentences could denote. Again, there can be at most one thing denoted by all true sentences. And, patently, no one thing may serve as the meaning of such diverse sentences as ‘Abe Lincoln was assassinated,’ ‘Ottawa is the capital of Canada,’ ‘Russia is bigger than Uruguay,’ etc.

So, one metaphysical idea is that facts are complexes built from commonplace objects, properties and relations. Another is that propositions exist

independently of language, and are what sentences stand for. Each of these has been argued to fall prey to the ‘slingshot.’ Another metaphysical view under attack has to do with notions such as necessity, possibility, causation, and temporal order. (Call these ‘MCT properties,’ for modal-causal-temporal.) At first glance, it seems that whether an object has an MCT property does not depend upon what the object is called. Call this its ‘first feature.’ Just as the rose smells sweet under any name, the rose is **necessarily** a flower no matter what it’s called; and its thorns **caused** this little cut on my hand, no matter what it’s called; and it bloomed **before** July 1, no matter what it’s called. MCT properties, that is, seem to be sensitive to the nature of the thing itself, not to how we speak about it. Even more obviously, just because one object has the property of being necessarily a flower, it doesn’t follow that every object does. And just because something caused that cut on my hand doesn’t mean that any old thing did. Similarly for temporal order: that the rose bloomed before July 1 doesn’t entail that anything you wish to pick happened before July 1. Call that its ‘second feature.’ Curiously, the slingshot argument has been used to show that, given an added complication about logical equivalence that will be explained below, these two supposed features of MCT properties can’t both apply. If we insist that not every truth is necessary, that not every event caused such-and-such, that not every event is temporally prior to so-and-so, then we must grant that whether something has an MCT property depends on what name is used for it. In this latter respect, MCT properties must be radically different from smelling sweet. (Terminological note: In what follows, I’ll speak of ‘operators’ when I mean ‘words that either modify one sentence, or connect two sentences.’ Thus all of ‘necessarily,’ ‘possibly,’ ‘because’ and ‘before’ are operators in my sense. Note also that the results to be discussed do not merely apply to words that modify and connect sentences: the arguments presented could easily be extended to expressions that combine sentences with subsentences, e.g., ‘[_S Juana died] before [_{NP} the American Civil War]’ combines a sentence with a noun phrase. To keep things simple, however, I will focus on operators combining or modifying sentences.)

Substitution *Salva Veritate*

I have quickly canvassed three targets of the slingshot: world-bound facts, the proposition as sentence meaning, and the claim that MCT properties have the two features introduced just above. Eventually I will explain how technical points about substitutivity *salva veritate* – the second element in the article’s

title – can be used to call facts *et al.* into question. But I need to start with what substitution *salva veritate* is, the varieties of substitutional contexts (i.e., for singular terms and for sentences), constraints on such substitution, etc.

I will begin with substitutivity of singular terms. Shakespeare famously said that a rose by any other name would smell as sweet. This certainly seems right: you don't change the smell of a rose just by renaming it. We can put his point about roses less eloquently as: 'You may substitute any coreferential name for "This rose" in "This rose smells sweet" and preserve truth.' Though wordy, this also seems right, and for just the same reason: a name change doesn't yield an odor change. Nor is '—— smells sweet' an isolated example. A dog by any other name would weigh just as much, would have the same number of hairs, would have the same size ears, etc. This is substitution *salva veritate*: 'substitution while preserving truth.'

Interestingly, not all contexts are like '—— smells sweet' or '—— weighs 28lb.' Sometimes when you change the label of an object, you don't preserve the truth of the whole sentence. Consider an example adapted from W. V. O. Quine:

- (1) Andre the Giant was so called because of his size
- (2) André Roussimoff was so called because of his size

Sentence (1) is true: the famous wrestler adopted that name precisely because he was so big. But sentence (2) is false. Surprisingly, this is the case even though 'Andre the Giant' and 'André Roussimoff' refer to the very same person. So, unlike roses and being sweet smelling, a wrestler by any other name would not automatically be so called because of his size; if he happens to have the property of being so called because of his size under all of his names, that would be the merest coincidence.

Of course what's special and different about '—— was so called because of his size' is that it explicitly makes reference to the name of the person being discussed: this curious predicate applies to linguistic things, i.e., names, not (just) to the person herself. That's why you can't put in any name you like for Andre in (1): because the sentence talks about words, specifically about names. We can see this point still more clearly with quotation marks. As it happens, the city of Toronto is also known as Hog Town. These two names refer to the same place. (Toronto used to be a major center for pork processing.) Yet (3) is true, while (4) is false:

- (3) 'Toronto' contains exactly three vowels
- (4) 'Hog Town' contains exactly three vowels

In this case it should be no surprise that you cannot substitute coreferring names in the context "—— contains exactly three vowels," because this predicate is obviously about the name, not about its referent. In contrast, '—— smells sweet' does not make reference to the linguistic item employed, but is instead wholly about the flower – that's why you can substitute whatever name you like. And '—— is so called because of his size' makes reference to both the denotation and the name: it's Andre the man who is being discussed, but 'so called' makes reference to his name as well. In sum, we have contexts which don't allow substitution of coreferring names *salva veritate* (both the kind which is just about words, as in quotation mark contexts, and the kind which is about words and nonwords, as in '—— was so called'), and contexts which do allow substitution *salva veritate* (the '—— smells sweet' and '—— weighs 28lb' kind).

The excursus into substitution principles continues. I've considered one kind of thing that can be substituted, namely singular terms. And I've considered one constraint on truth-preserving substitution, namely that the predicate apply to the thing denoted, not to the words that denote. Another kind of substitution deals not with names (such as 'Andre' and 'Toronto'), but rather with sentences. In some linguistic contexts, you can preserve truth by substituting sentences that have the same truth value. This works, for instance, with 'and,' 'or,' and the other truth functional connectives familiar from classical logic. To take one example, sentence (5) is true because both of its conjuncts are true. And since (6) is true as well, sentence (7) must be true, precisely because (7) results merely from substituting the true sentence (6) in for the second conjunct of (5).

- (5) Ottawa is the capital of Canada and Toronto is west of Ottawa
- (6) Vancouver is west of Edmonton
- (7) Ottawa is the capital of Canada and Vancouver is west of Edmonton

But many linguistic contexts don't preserve truth when one interchanges sentences that happen to have the same truth value. Take 'Just about everyone knows that ——.' Sentence (8), when embedded in this context, yields the true (9):

- (8) Two plus two is four
- (9) Just about everyone knows that two plus two is four

Now, sentences (6) and (8) have the same truth value: they are both true. Yet if we substitute (6) for (8), in 'Just about everyone knows that ——,' the result is

(10), which is not true. Canada's geography just isn't that widely known.

- (10) Just about everyone knows that Vancouver is west of Edmonton

So, unlike in the case of 'and,' we can go from the true (9) to the false (10) by substituting one true sentence for another. Thus, truth is **not** preserved under substitution, in the scope of 'Just about everyone knows that —.' This provides an example of not being able to substitute material equivalents *salva veritate*.

One last substitution principle. There are some contexts which allow substitution of logically equivalent sentences *salva veritate*. One example is 'entails.' Any two sentences which are logically equivalent entail the same things. Thus given the truth of (11) and the logical equivalence of (12) and (13), one can derive (14) by substitution.

- (11) That it's not the case that either Clinton is dead or Bush is dead entails that it's not the case that Clinton is dead
- (12) It's not the case that either Clinton is dead or Bush is dead
- (13) It's not the case that Clinton is dead and it's not the case that Bush is dead
- (14) That it's not the case that Clinton is dead and it's not the case that Bush is dead entails that it's not the case that Clinton is dead

But not all verbs are like this. Consider words like 'know,' 'believe,' 'expect' and so on – so-called propositional attitude verbs. Not only can one not automatically substitute true-for-true sentences, while preserving the truth of the whole, one cannot even substitute a **logically equivalent** sentence while guaranteeing truth. One way to see this is to consider that there are extremely complicated, and also very simple, ways of expressing claims which are logically equivalent. Put in the simple way, a child might know that the claim is true; but put in the extremely complex way, he might not. For instance, little Billie, a five-year-old, might expect that it will snow in January. That's simple enough for a child that age. But (15) is logically equivalent to the very complex (16):

- (15) It will snow in January
- (16) $\{x: x = x \ \& \ \text{It will snow in January}\} = \{x: x = x\}$

Now, Billie might well expect the former, yet not at all expect the latter.

Since logical equivalence of sentences of the form (15) and (16) will play a key role below, let me say rather more about it. Take ' $\{x: x$ is an odd number less than 27}' as an example. It refers to a set – specifically, a certain set of odd numbers. For what follows, it's

helpful to think of belonging to a set as involving meeting, or failing to meet, one or more conditions. For instance, an object belongs to $\{x: x$ is an odd number less than 27} if it is both an odd number, and less than 27. An object fails to belong to the set if it fails to meet either of these. Taking membership to involve meeting or failing to meet conditions, consider now the set $\{x: \text{Ottawa is the capital of Canada}\}$. At first glance this looks like an odd set, but the general rule still applies: an object belongs to this set if it meets the condition that Ottawa is the capital of Canada. Now, since every object meets that condition, every object belongs to that set. With this in mind, consider the first half of (16). This phrase stands for the set of x s such that x is self-identical and it will snow in January. So, there are two conditions that must be met by an object, in order for it to be in the set: the object must be self-identical, and it must be the case that it will snow in January. The first condition is trivially satisfied by every object, however. So, in a way parallel to $\{x: \text{Ottawa is the capital of Canada}\}$, whether an object gets into the set depends wholly upon whether it will snow in January: if it will snow in January, every object meets the two conditions for inclusion; if it will not snow in January, no object meets them. In this way, ' $\{x: x = x \ \& \ \text{It will snow in January}\}$ ' comes to denote the set of all individuals, if it will snow in January. Now, the set of all individuals is also, of course, what ' $\{x: x = x\}$ ' denotes. So the statement of their numerical identity, i.e., (16), is true if it will snow in January. On the other hand, if it won't snow in January, then ' $\{x: x = x \ \& \ \text{It will snow in January}\}$ ' denotes the null set: no object satisfies the two conditions for inclusion in this set, viz., that it be self-identical and that it will snow in January. Hence, if it won't snow in January, the statement of identity between ' $\{x: x = x \ \& \ \text{It will snow in January}\}$ ' and ' $\{x: x = x\}$ ' is false: the empty set, which is what the left-hand side of the equation would denote, does not equal the set of all objects, which is what the right-hand side denotes.

In short, the two sentences (16) and 'It will snow in January' are true and false together in every circumstance. So, they are logically equivalent. Nevertheless, Little Billie, I said, may well expect that it will snow in January; but, surely, it's not the case that little Billie expects that the set whose members are such that they are self-identical and it will snow in January is identical with the set whose members are self-identical! So, substitution of (16) for the logically equivalent (15), in the scope of 'expects that —,' does not necessarily preserve truth. If truth is preserved, it's because of a mere coincidence, namely that the person just happens to expect both things.

So, we have sentence operators like ‘and’ that allow substitution *salva veritate* of merely materially equivalent sentences – i.e., of sentences which just happen to have the same truth value. And we have sentence operators like ‘know’ and ‘expect’ that don’t allow that kind of substitution, and don’t even allow substitution of logically equivalent sentences. This completes my explanation of substitution *salva veritate* of sentences. We also surveyed substitution of singular terms. Many contexts allow this: ‘—— weighs 28 lb’ and ‘—— smells sweet.’ Some do not: ‘—— was so called because of his size.’ The next step is to put the notion of substitution *salva veritate* to work.

The Argument: The Slingshot Itself

Let’s take stock. In the first section we encountered three metaphysical views. The first two involved facts and factlike propositions: that facts are made up of objects, properties, and relations, that factlike propositions exist and serve as the meanings of natural language sentences. The third involved MCT properties having two features: of applying to objects themselves, and not applying to all truths.

Given the concepts introduced above, we can now rephrase this third metaphysical view, and add a third presumption about logical equivalence:

- i. Coreferential singular terms may be substituted one for another within the scope of MCT words without altering the truth of the whole sentence;
 - ii. Logically equivalent sentences may be substituted one for another within the scope of MCT words without altering the truth of the whole sentences.
- But
- iii. Sentences which are merely materially equivalent – i.e., which just happen to have the same truth value – may not be so substituted.

To introduce one last piece of terminology, this is to say that MCT words aren’t hyperintensional (i.e., they meet both (i) and (ii)) but they also aren’t transparent (i.e., they meet (iii)).

Before providing the language-based argument that none of these metaphysical views are really true, let’s quickly recall why it matters. What is attractive about the first two metaphysical views? Why worry about giving them up? First, as stressed above, a rose by any other name would smell as sweet. Second, we can’t have every linguistic change in the sentence giving rise to a different proposition. Third, and related to the second, we want the same proposition to give the meaning of sentences in different languages. And

why is it attractive to say that MCT words satisfy (i)–(iii)? Well, it would seem that ‘necessarily,’ ‘possibly,’ and other modal modifiers would allow substitution fairly freely, since, as noted, they don’t (seem to) apply to linguistic items. Like ‘—— smells sweet,’ these terms seem to be entirely about things, not at all about words. It’s Shakespeare’s rose point once again. For example, starting with modal operators, if Andre the Giant was necessarily a human being (and it seems that he was), then André Roussimoff was necessarily a human being too: it doesn’t matter what name we use for him, **he** is just as necessarily human. Similarly for causal operators: if Andre the Giant died because he had a heart attack, then André Roussimoff died because he had a heart attack. The phrase ‘—— died because he had a heart attack’ is about the person alone, regardless of how that person is denoted. Nor, turning to the temporal ‘before,’ could Andre the Giant die before Clinton was president, while André Roussimoff did not. As with ‘because,’ ‘before’ just doesn’t seem to work like ‘—— was so called because of his size’ and “——” contains exactly three vowels.’ It seems to work like ‘—— smells sweet’ and ‘—— weighs 28lb.’ It is this kind of reasoning which supports the claim that ‘necessary,’ ‘possibly,’ ‘before,’ and ‘because’ meet condition (i): coreferring singular terms may be substituted one for another, within the scope of **these** words, without altering the truth of the whole sentence. Moreover, unlike ‘know,’ ‘expect,’ and ‘believe,’ logically equivalent facts are either both necessary, or both not necessary, either both possible, or both not possible, either both before a certain event, or not. Thus, MCT words meet (ii) as well. So, these operators do allow substitution of the first two kinds – they are not hyperintensional. Yet, or so it would seem, you can’t substitute any old true sentence for ‘Andre the Giant is human’ in ‘It is necessary that Andre the Giant is human’: substitution of material equivalents is not sanctioned in the scope of modal modifiers. Nor can you substitute any old true sentence for ‘André Roussimoff died of a heart attack’ in ‘André Roussimoff died of a heart attack before Clinton was president’; nor in ‘Little Billie cried because André Roussimoff died of a heart attack.’ So MCT words meet (iii) too. (One might sum up by saying that MCT words are a mite promiscuous in terms of what substitutions they’ll allow, but it’s not a free-for-all either.)

Despite their attractiveness, however, and contrary to a once widely assumed semantics, if the slingshot argument works, MCT words either must not allow substitution of coreferring names or logically equivalent sentences, or they must allow substitution of sentences that just happen to be true together. And, despite the attractions of the metaphysical views,

there can be at most one world-bound fact, and it patently cannot serve as the meaning of all sentences!

The argument, at last. As the title of this article suggests, the ‘slingshot’ in question is not a Y-shaped frame spanned by an elastic; it is, instead, an argument. It was dubbed ‘the slingshot’ by Jon Barwise and John Perry, because it “is so small, seldom encompassing more than half a page, and employs such a minimum of ammunition” (Barwise and Perry, 1981: 398). Moreover, like the eponymous Y-shaped frame, it can, despite its modest make-up, be used to attack some very significant foes.

I will present the argument in two stages. First, I will give it in the abbreviated format one often encounters in journal articles and such. Second, I will offer a more extended version of the argument.

As Barwise and Perry (1981) and Neale (1995) both note, variations on the argument, in its very brief form, seem to have been first formulated independently by Alonzo Church (1943: 299–300, 1956: 24–25) and Kurt Gödel (1944: 128–129). But I will focus on the best-known variant of the argument, that due to Donald Davidson (1967a: 19). Since his presentation of the argument is especially condensed, and has left so many readers puzzled, I will cite it in full, and then try to explain it. (NB: I have altered Davidson’s numbering, and his logicomathematical notation, to bring it in line with what appears above.)

Davidson writes:

The difficulty follows upon making two reasonable assumptions: that logically equivalent singular terms have the same reference, and that a singular term does not change its reference if a contained singular term is replaced by another with the same reference. But now suppose that ‘R’ and ‘S’ abbreviate any two sentences alike in truth value. Then the following four sentences have the same reference:

- (a) R
- (b) $\{x: x = x \ \& \ R\} = \{x: x = x\}$
- (c) $\{x: x = x \ \& \ S\} = \{x: x = x\}$
- (d) S

For (a) and (b) are logically equivalent, as are (c) and (d), while (c) differs from (b) only in containing the singular term ‘ $\{x: x = x \ \& \ S\}$ ’ where (b) contains ‘ $\{x: x = x \ \& \ R\}$ ’ and these refer to the same thing if S and R are alike in truth value (Davidson, 1967a: 19).

As two generations of students can attest, this argument goes by very quickly. It is the ‘slingshot’ in its purest form. The first two sentences of the quotation essentially lay out, though in rather different terminology, conditions (i) and (ii) above. This is obscured by two things. First, because of the context in which he is writing, Davidson doesn’t explicitly limit his claims to sentences occurring within the scope of

words like ‘necessarily,’ ‘possibly,’ ‘before,’ and ‘because.’ (For a variant of the argument which is more explicitly restrictive along those lines, see Davidson, 1967b: 152–153, and also Davidson, 1969: 42.) Second, the relation between these first two sentences and conditions (i) and (ii) is obscured by the fact that Davidson is here assuming, for the sake of argument, that **sentences refer**, and hence just are a special kind of singular term; and that they refer specifically to **truth values**. Thus, when he says “a singular term does not change its reference if a contained singular term is replaced by another with the same reference,” this entails (i) as a special case: the special case where the containing ‘singular term’ is a sentence, and the contained singular term is a name. And when he says “logically equivalent singular terms have the same reference,” this yields, given his dictum about constant reference for the whole given constant reference of the parts, (ii): that logically equivalent sentences may be substituted, *salva veritate*, within larger sentences. Thus Davidson is here arguing that, despite appearances, any operator Φ , if it permits substitution of coreferential singular terms and substitution of logical equivalents within its scope, also permits substitution of sentences which are merely materially equivalent, i.e., which simply happen to share the same truth value. That is, using the terminology introduced above: if Φ is not hyperintensional, then it is transparent.

Let’s now unpack this. As I reconstruct it, the slingshot argument consists of two assumptions – which together essentially say that Φ is nonhyperintensional – plus three ‘lemmas’ based on logical relations. The assumptions are:

- A1. Substitution of **coreferential singular terms** in the scope of Φ will not change the truth value of the whole.
- A2. Substitution of **logically equivalent sentences** in the scope of Φ will not change the truth value of the whole.

The first two lemmas state logical equivalences:

L1. The sentence ‘ $\{x: x = x \ \& \ R\} = \{x: x = x\}$ ’ is logically equivalent to ‘R.’

Proof: If ‘R’ is true, then the left-hand side of the equation refers to the set of all individuals, because everything is such that it is self-identical and R obtains. And that’s what the right-hand side refers to as well. So, the equation as a whole is true, if ‘R’ itself is true. If ‘R’ is false, then the left-hand side of the equation refers to the empty set: if ‘R’ is false then nothing is such that it is self-identical and R obtains. But that’s not what the right-hand side refers to: the right-hand side still refers to the set of all individuals.

So, the equation as a whole is false, if ‘R’ is false. Thus the two sentences are logically equivalent.

L2. The sentence ‘ $\{x: x = x \ \& \ S\} = \{x: x = x\}$ ’ is logically equivalent to ‘S.’

Proof: Same as for L1.

The third lemma establishes a coreference relation:

L3. The singular term ‘ $\{x: x = x \ \& \ R\}$ ’ is coreferential with the singular term ‘ $\{x: x = x \ \& \ S\}$.’

Proof: Given that both sentences ‘S’ and ‘R’ are true, both of the singular terms in L3 refer to the set of all individuals. That is, everything is such that [it is self-identical and R]; and everything is such that [it is self-identical and S].

From the two assumptions about the nonhyperintensionality of Φ , and making use of the three lemmas about set theoretic relations, we will derive that Φ is transparent. The derivation, in effect, takes us to $\Phi(S)$ from $\Phi(R)$, for any two true sentences. This will show that mere material equivalence is, despite appearances, sufficient for substitution *salva veritate* within the scope of nonhyperintensional operators such as Φ . Thus, the general result is that if a context isn’t hyperintensional, it is transparent.

The derivation runs as follows. We start with (17):

(17) $\Phi(R)$

Given A2 and L1, we can substitute ‘ $\{x: x = x \ \& \ R\} = \{x: x = x\}$ ’ for the logically equivalent ‘R’ in (17) while preserving truth. This yields:

(18) $\Phi(\{x: x = x \ \& \ R\} = \{x: x = x\})$

Given A1 and L3, we don’t alter the truth value of (18) by substituting ‘ $\{x: x = x \ \& \ S\}$ ’ for the coreferential singular term ‘ $\{x: x = x \ \& \ R\}$ ’: these singular terms refer to the same set, i.e., the set of all objects, and we may thus substitute one name for the other. We may thus move from (18) to (19):

(19) $\Phi(\{x: x = x \ \& \ S\} = \{x: x = x\})$

Now, the final step in deriving $\Phi(S)$ from $\Phi(R)$ is the appeal to logical equivalence once again. Given A2 and L2, we can derive our desired target sentence (20) from (19):

(20) $\Phi(S)$

Being derivable in this way, (20)’s truth value must be the same as the original (17). The upshot is that if assumption 1 and assumption 2 are true with respect to a modifier/connective Φ (i.e., if Φ is not hyperintensional), then (20) may be derived from (17), for **any** true sentences ‘R’ and ‘S.’ Hence Φ , insofar as it’s not hyperintensional, does allow substitution of material equivalents after all: it is a transparent operator.

It’s worth stressing: Such a derivation can be constructed for **any** connective or modifier meeting conditions (i) and (ii): ‘necessarily,’ ‘possibly,’ ‘before,’ and ‘because,’ but also ‘the fact that — caused little Billie to cry’ and ‘the sentence “It will snow in January” stands for the proposition that —,’ and so on. So, the result isn’t merely about MCT properties – the third metaphysical view of the three surveyed in the first section – but includes the broader ones that there can be at most one world-bound fact, and that sentences cannot have factlike items as their denotations. Given the importance of these broader results, let us revisit the points in detail.

Aiming the Slingshot at Facts, and Factlike Things

Davidson and others have found the technical result important because they take it to show that sentences cannot stand for ‘facts,’ or factlike things. Or, more precisely, they cannot when facts are taken to be complexes of ordinary objects, properties, and relations. Indeed, they take it to show that such facts in the plural simply do not exist. The connection between the just-presented technical result and these broader theses is this: if there were multiple world-bound facts, and if sentences stood for them (or something like them, e.g., propositions), then expressions of the form (21) and (22) would have to meet conditions (i)–(iii). But we have just seen an argument that no expression can do this.

(21) The fact that Ottawa is the capital of Canada is different from the fact that —

(22) ‘Ottawa is the capital of Canada’ stands for the proposition that —

Here is the argument specifically against propositions, as I reconstruct it. (It should be straightforward to run the same sort of argument with respect to (21) and facts.) According to the view under consideration, which has facts/propositions containing ordinary objects and such, you don’t change from one proposition to another just by changing the name of the thing described. (As noted above, there are other ways of thinking about facts, and factlike things such as propositions, but the view that facts contain commonplace objects is the most intuitive for reasons already sketched.) Thus, changing the name only matters when the claim is actually about words, as in (1) and (3) above – and claims can’t always be about words; facts and propositions are to be autonomous from sentences. These provide good reasons why facts and propositions should be world bound, which in turn entails that the context in (22) must

allow substitution of coreferring singular terms. For quite similar reasons, it seems that two sentences which ‘say the same thing,’ but in different words, shouldn’t correspond to distinct facts/propositions; hence logically equivalent sentences should, it may seem, be substitutable in (22) without altering the truth of the whole. In this way we support variants on A1 and A2, here applied to the case (22). But once we have these two premises we can derive, using the argument above, that truth is retained if we substitute any true sentence.

Let’s walk through the derivation with an example, namely (23):

- (23) ‘Ottawa is the capital of Canada’ stands for the proposition that Ottawa is the capital of Canada

Suppose (23) is true, as it surely must be if sentences stand for factlike things. Given the logical equivalence of ‘ $\{x: x = x \ \& \ S\} = \{x: x = x\}$ ’ with S itself, for any sentence S , by A2 it follows that:

- (24) ‘Ottawa is the capital of Canada’ stands for the proposition that $\{x: x = x \ \& \text{Ottawa is the capital of Canada}\} = \{x: x = x\}$

Given that the singular term ‘ $\{x: x = x \ \& \ S\}$ ’ is coreferential with the singular term ‘ $\{x: x = x \ \& \ R\}$,’ as long as R and S are both true, we can apply this generalization to ‘Ottawa is the capital of Canada’ and ‘André Roussimoff died of a heart attack’ (both of which are true) to establish that:

- (25) ‘ $\{x: x = x \ \& \text{Ottawa is the capital of Canada}\}$ ’ is coreferential with the singular term ‘ $\{x: x = x \ \& \text{André Roussimoff died of a heart attack}\}$ ’

Now, we apply substitution of coreferring singular terms to (24). The result of substituting ‘ $\{x: x = x \ \& \text{André Roussimoff died of a heart attack}\}$ ’ for ‘ $\{x: x = x \ \& \text{Ottawa is the capital of Canada}\}$ ’ is:

- (26) ‘Ottawa is the capital of Canada’ stands for the proposition that $\{x: x = x \ \& \text{André Roussimoff died of a heart attack}\} = \{x: x = x\}$

The final step is to note that the complex identity statement about sets is logically equivalent to ‘André Roussimoff died of a heart attack.’ So, using substitution of logical equivalents a second time, now applied to (26), we can derive (27):

- (27) ‘Ottawa is the capital of Canada’ stands for the proposition that André Roussimoff died of a heart attack

In sum, given that facts and propositions are to be language independent in certain ways, “Ottawa is the capital of Canada” stands for the proposition that —’ should not be hyperintensional. But we

can use the slingshot to show that if the context in (22) is not hyperintensional, then it is transparent. That’s disastrous, however, because then this sentence ‘stands for’ any old true proposition! One can run precisely the same argument, beginning with (21), to show that there is only one world-bound fact.

Responses to the Slingshot Argument

It seems, very much contrary to initial appearances, that modal, causal, and temporal words lack at least one of these properties:

- i. Coreferential singular terms may be substituted one for another within the scope of these words without altering the truth of the whole sentence;
- ii. Logically equivalent sentences may be substituted one for another within the scope of these words without altering the truth of the whole sentences;
- iii. Sentences which are merely materially equivalent – i.e., which just happen to have the same truth value – may not be so substituted.

Also, because of substitution patterns like this, we seem also to be forced to give up world-bound facts and factlike propositions as the denotations of sentences. How is a metaphysician to respond?

One simply cannot give up (iii) as a condition on ‘the fact that —’ and such. That’s because, put in terms of an example, this would allow ‘the fact Ottawa is the capital of Canada’ to stand for the fact that Toronto is larger than Halifax! There are, however, at least three ways of saving MCT properties, facts, and factlike things such as propositions, in the face of the slingshot: two ways corresponding to (i) and one way corresponding to (ii). I will take them in reverse order.

First, one can reject the idea that logically equivalent sentences really do stand for a single fact, or factlike proposition. This is explicitly suggested by Barwise and Perry (1981). The proposal is that sentences with different subject matters do not stand for the same fact, even if they are true in precisely the same circumstances. Now (15) and (16), though logically equivalent, clearly have different subject matters, since only the latter talks about sets. So these sentences need not be taken to stand for the same fact. Granted, this makes facts, which are supposed to be built from ordinary elements of the world on the world-bound conception, look a bit more like the linguistic items that stand for them: facts get individuated in terms of meaning-related criteria such as ‘subject matter.’ However, this need not jeopardize the distinction between sentences and their meanings. For instance, we can still insist that sentences in different languages can stand for the same fact – as long as they have the same subject matter. And we can even

insist that sentences made up of coreferential words, put together in the same way, stand for the same fact. Maybe even transformed sentences can stand for the same fact, if the transformation does not alter the subject matter: e.g., ‘Moe kissed Juana’ might stand for the same fact as ‘Juana was kissed by Moe.’ One thus saves world-bound facts, and propositions, by rejecting (ii). (It’s less obvious that this move allows MCT properties to have the three features we want; but explaining the ins and outs of that would take us too far afield.)

Second, one can reply to the slingshot argument by denying that (i) really applies. This ‘it doesn’t apply’ move can be pursued in two different ways. Those who follow Frege (1892) maintain that you only have the same fact, or proposition, when not just the referent, but also the sense of the name, is the same. Famously, Frege introduced a two-level semantics, with guises-of-things occupying the level of sense, and the things themselves occupying the level of reference. Crucially for present purposes, being the same fact or proposition is supposed by Frege to require being the same at both levels. So, for example, ‘Elton John lives in England’ and ‘Reg Dwight lives in England’ don’t really correspond to the same proposition, because the two names differ in sense – even though these two names do refer to the same singer. This is to say that (i) ‘doesn’t apply’ in the sense that it’s false: coreferring singular terms can give rise to different facts/propositions. It should be clear that making this reply forces one to give up the world-bound conception of facts and factlike things. It is now not objects themselves, but objects described one way or another, that become the components of facts and propositions. This notion of proposition, with different propositions corresponding to the same referents arranged in the same way, is safe from the slingshot. As is the associated notion of fact. For this notion of fact/proposition allows one to reject substitution of coreferential singular terms in the contexts in question – and without that, the slingshot argument cannot get going.

Many contemporary philosophers find this Fregean approach unacceptable, however, for reasons already sketched: it seems like it’s the rose itself which smells sweet, not the rose under a guise; and it’s the man himself who died of a heart attack; and so on. So it seems, there should be no more to facts than perfectly ordinary objects, properties and relations. Not wanting to abandon the world-bound conception of facts, their alternative response to the slingshot argument is to insist that (i), though it is true, cannot be used as the proponent of the slingshot wishes to, because things like ‘ $\{x: x = x \ \& \ \text{André Roussimoff died of a heart attack}\}$ ’ aren’t really singular terms. It is in this

sense that condition (i) doesn’t apply. As Russell (1905) insisted, say these theorists, such expressions are complex definite descriptions whose role is quantificational, not referential: ‘the set of objects such that ...’ (which is what this mathematical expression actually means), is not namelike; it is instead more like the quantifiers ‘every set of objects such that ...’ and ‘some set of objects such that ...’. And condition (i) above, along with A1, which derives from (i), do not say anything about being able to substitute quantificational expressions *salva veritate*: A1 and (i) only apply to expressions whose function is to pick out an object, without describing it. Put in terms of examples, while it’s quite true that ‘Elton John is a singer’ and ‘Reg Dwight is a singer’ both stand for the same fact, since these involve two genuine names for the entertainer, it nevertheless is not the case that the description-involving sentences ‘The Queen of England lives in London’ and ‘Canada’s head of state lives in London’ stand for the same fact. Descriptions do not ‘merely pick out the object.’ Indeed, say these followers of Russell, what the sentence containing ‘the Queen of England’ really means is: There exists exactly one queen of England, and every queen of England lives in London. Crucially, therefore, the introduction of things like ‘ $\{x: x = x \ \& \ \text{André Roussimoff died of a heart attack}\}$ ’ takes us out of the realm of names (where [i] and A1 apply), and into the realm of descriptions (where they don’t). Thus, when one appeals to A1 *et al.* – to move from (18) to (19) in the general case, and from (24) to (26) in the specific case of “S” stands for the proposition that —’ – a fallacy is committed. (Neale, 1995, following Gödel, 1944, gave roughly this reply to the slingshot. Barwise and Perry, 1981 made related points.)

To summarize, then, the slingshot is an argument that deploys very modest machinery to take on several very important metaphysical views. The views include the two broad ones, that there are world-bound facts in the plural, and that what sentences stand for are factlike things, and a related more technical view about what kind of sentence-modifying and sentence-connective operators there can be. The key move in the argument is to start with an arbitrary sentence containing ‘R’ and one of the problematic operators (‘necessarily,’ ‘before,’ ‘because,’ ‘it’s a fact that —,’ etc.), to create a logically equivalent sentence that has ‘ $\{x: x = x \ \& \ R\} = \{x: x = x\}$ ’ in the scope of the suspect operator. This latter sentence *ipso facto* contains the singular term ‘ $\{x: x = x \ \& \ R\}$,’ which, assuming both ‘R’ and ‘S’ are true, is coreferential with ‘ $\{x: x = x \ \& \ S\} = \{x: x = x\}$.’ Hence, one can deploy the substitution of logical equivalents and the substitution of coreferring singular terms to derive another arbitrary materially equivalent sentence now containing not

'R' but 'S' in the scope of the operator. This shows that if the operator is not hyperintensional, then it's transparent. The three ways to block this argument are (a) to give up substitution *salva veritate* of logical equivalents in the scope of the operator, (b) to follow Frege, and give up substitution *salva veritate* of coreferential singular terms (and with it the world-bound conception of facts) and (c) to insist that substituting expressions of the form ' $\{x: x = x \ \& \ R\} = \{x: x = x\}$ ' is not, in fact, a matter of substituting singular terms, since such expressions are not referential at all, but are instead quantificational expressions.

Pulling back from the details, the slingshot illustrates how careful reflection on a linguistic phenomenon can contribute to debates in metaphysics. In particular, we have taken as our example the role of various principles of substitution *salva veritate* in attacks on facts, propositions, and views about the properties of modal, causal, and temporal properties. The possible replies to the slingshot highlight still further, I think, the importance of linguistic details when discussing metaphysics.

Modal Logic

M Cresswell, The University of Auckland, Auckland, New Zealand

In classical propositional logic, all the operators are truth-functional. That is to say, the truth or falsity of a complex formula depends only on the truth or falsity of its simpler propositional constituents. Take the monadic operator \sim . This is interpreted to mean 'it is not the case that', and its meaning is defined by Table 1, called a truth table, in which 1 represents 'true' and 0 represents 'false'. This operator is truth-functional because the truth value of the complex proposition it forms is determined by the truth value of the proposition it starts with. If α has the value 1, then $\sim\alpha$ has 0. If α is 0, $\sim\alpha$ is 1. (I use standard operators for propositional logic: \sim for negation, \vee for (inclusive) disjunction, \wedge for conjunction, \supset for

(material) implication and \equiv for (material) equivalence.) Modal logic is concerned with understanding propositions about what **must** or about what **might** be the case, and it is not difficult to see how we might have two propositions alike in truth value, both true, say, where one is true and could not possibly be false and the other is true but might easily have been false. For instance it must be that $2 + 2 = 4$, but, although it is true that I am writing this entry, it might easily not have been. Modal logic extends the well-formed formulae (wff) of classical logic by the addition of a one-place sentential operator L (or \Box) interpreted as meaning 'it is necessary that'. Using this operator, an operator M (or \Diamond) meaning 'it is possible that' may be defined as $\sim L\sim$. The notation L and M for the necessity and possibility operators dates from Feys (1950) (for L) and Becker (1930) (for M). (For a history of notation, see Hughes and Cresswell, 1968: 347–349). The use of \Box for the necessity operator is due to F. B. Fitch and first appears in Barcan (1946); the use of \Diamond for M dates from Lewis and Langford (1932). In fact, any one of L or M can be taken as primitive and the other defined in terms of it. Another operator that may be defined in terms of L and M is the operator Q (or ∇), where $Q\alpha$ means that α is

Table 1 Truth table

$\sim\alpha$
01
10

contingent, that is, neither necessary nor impossible. $Q\alpha$ may be defined as $\sim L\alpha \wedge M\alpha$. Many uses of *possible* in natural language suggest that what is possibly true is also possibly false, and those uses are better served by Q than by M .

The modern development of modal logic dates from 1912 when C. I. Lewis published the first of a series of articles and books (culminating in Lewis and Langford, 1932) in which he expressed dissatisfaction with the notion of material implication found in Whitehead and Russell's (1910) *Principia mathematica*. In the system of *Principia mathematica* – indeed in any standard system of propositional calculus (PC) – there are found the theorems:

- (1) $p \supset (q \supset p)$
- (2) $\sim p \supset (p \supset q)$

The sense of (1) is often expressed by saying that if a proposition is true, any proposition whatsoever implies it; the sense of (2) is often expressed by saying that if a proposition is false, it implies any proposition whatsoever. Lewis did not wish to reject these. He argued that they are “neither mysterious sayings, nor great discoveries, nor gross absurdities” (Lewis, 1912: 522), but merely reflect the truth-functional sense in which Whitehead and Russell were using the word *imply*. But he also maintained that there is a sense of *imply* in which when we say that p *implies* q we mean that ‘ q follows from p ’ and that in this sense of *imply* it is not the case that every true proposition is implied by any proposition whatsoever or that every false proposition implies any proposition whatsoever. A brief account of the early history of modal logic is found in Hughes and Cresswell (1968: pt. 3, with Lewis's contributions documented in Chaps. 12–13).

Until the early 1960s, modal logics were discussed almost exclusively as axiomatic systems without access to a notion of validity of the kind used, for example, in the truth-table method for determining the validity of wff of the classical propositional calculus. The semantical breakthrough came by using the idea that a necessary proposition is one that is true in all possible worlds. But whether another world counts as possible may be held to be relative to the point we are at. So an interpretation for a modal system would consist of a set W of possible worlds and a relation R of accessibility between them – where the worlds accessible from a given world are often described as the worlds that world can see. For any wff α and world w , $L\alpha$ will be true at w iff α itself is true at every w' such that wRw' . Put formally, a frame is a structure $\langle W, R \rangle$ in which W can be any class at all, although its members are often called ‘worlds’ or ‘indices,’ and R is a relation between them. A model can then be based on that frame by

adding a value assignment V . V assigns to each variable p a truth value in each world. If we read $V(p, w) = 1$ (0) as ‘ V assigns p the value true (false) in world w ’, then we may, for instance, define the truth table for \sim so that $V(\sim\alpha, w) = 1$ if $V(\alpha, w) = 0$, and 0 otherwise, and we may define the disjunction operator \vee so that $V(\alpha \vee \beta, w) = 1$ iff either $V(\alpha, w) = 1$ or $V(\beta, w) = 1$. $V(L\alpha, w) = 1$ iff $V(\alpha, w') = 1$ for every w' such that wRw' . We define validity on a frame by saying that a wff α is valid on a frame $\langle W, R \rangle$ iff, for every model $\langle W, R, V \rangle$ based on $\langle W, R \rangle$ and for every $w \in W$, $V(\alpha, w) = 1$. The ideas that underlie this account of validity appeared in the late 1950s and early 1960s in the works of Kanger (1957), Bayart (1958), Kripke (1959, 1963), Montague (1960), and Hintikka (1961). Anticipations can be found in Wajsberg (1933), McKinsey (1945), Carnap (1946, 1947), Meredith (1956), Thomas (1962), and other works. An algebraic description of this notion of validity is found in Jónsson and Tarski (1951), although the connection with modal logic was not made in that article.

An axiomatic basis for a logical system consists of a selected set of wff, known as axioms, together with a set of transformation rules, licensing various operations on the axioms and on wff obtained from the axioms by previous applications of the transformation rules. The wff obtained from the axioms in this way, together with the axioms themselves, are known as the theorems of the system. The system of modal logic whose theorems are precisely the wff valid on every frame is known as the system K. This name, which has now become standard, was given to the system in Lemmon and Scott (1977) in honor of Saul Kripke, from whose work the way of defining validity for modal logic is mainly derived. The word ‘frame’ in this sense seems to have been first used in print in Segerberg (1968), but the word was suggested to him by Dana Scott. The axioms of K consist of all valid wff of PC together with the modal wff K:

$$L(p \supset q) \supset (Lp \supset Lq)$$

and it has the following three transformation rules:

- US (The Rule of Uniform Substitution): The result of uniformly replacing any variable or variables p_1, \dots, p_n in a theorem by any wff β_1, \dots, β_n , respectively, is itself a theorem.
- MP (The Rule of Modus Ponens, sometimes also called the Rule of Detachment): If α and $\alpha \supset \beta$ are theorems, so is β .
- N (The Rule of Necessitation): If α is a theorem, so is $L\alpha$.

Other modal systems may be obtained by adding extra axioms to K. Each of these will be a proper

extension of K (i.e., it will contain not only all the theorems of K but other theorems as well). Modal systems that contain K (including K, itself) together with US, MP, and N are commonly known as normal modal systems.

A wff valid on every frame is called K-valid, and the theorems of the system K are precisely those wff that are K-valid. It is important to be clear that this is a substantive fact and not something that is true by definition. To be a theorem of K is to be derivable from the axioms of K by the transformation rules of K; to be K-valid is to be valid on every frame, and the fact that a wff is a theorem of K iff it is K-valid is something we have to **prove**, not something we can assume. Similar remarks hold for extensions of K because different systems of modal logic can represent different ways of restricting necessity. It can then happen that whether a principle of modal logic holds or not can depend on the properties of the accessibility relation. We may have an axiomatic modal system defined without any reference to an account of validity and a definition of validity formulated without any reference to theoremhood in a system, and yet the theorems of that system are precisely the wff that are valid by that definition. To show that there is a match of this kind between a system and a validity definition, we have to prove two things: (1) that every theorem of the system is valid by that definition and (2) that every wff valid by that definition is a theorem of the system. If the first holds, we say that the system is sound, and if the second holds we say that it is complete, in each case with respect to the validity-definition in question.

The wff $Lp \supset p$ is not K-valid because it is not valid on a frame in which there is a world that is not accessible from itself. (Put p false in this world, and true everywhere else.) We could, however, add it as an extra axiom to obtain a system stronger than K itself. The system obtained by adding $Lp \supset p$ as a single extra axiom to K is usually referred to as T, and it has had a long history in modal logic dating from Feys (1937). Feys's own name for the system is 't' (it was first called 'T' by Sobociński, 1953). Feys derived the system by dropping one of the axioms in a system devised by Gödel (1933), with whom the idea of axiomatizing modal logic by adding to PC originates. Sobociński showed that T is equivalent to the system M of von Wright (1951); for this reason 'M' was occasionally used as an alternative name for T. T is K + T.

T: $Lp \supset p$

Although T is not valid on every frame it is valid on all frames in which R is reflexive, that is, frames in which every world is accessible from itself – where

wRw for every $w \in W$. It can be proved that the system T is sound and complete with respect to such frames. In any system containing T, $L\alpha$ is equivalent to $\alpha \wedge \sim Q\alpha$, and so necessity may be defined in terms of contingency. Without T, this cannot usually be done. An examination of when necessity can be defined in terms of contingency in systems that do not contain T may be found in Cresswell (1988).

If we interpret L as expressing obligatoriness (moral necessity), we are unlikely to want to regard $Lp \supset p$ as valid because it will then mean that whatever ought to be the case is in fact the case. There is, however, a formula that, like $Lp \supset p$, is not a theorem of K but that, under the moral interpretation, it is plausible to regard as valid, and that is the wff $Lp \supset Mp$. If Lp means that it is obligatory that p , then Mp will mean that it is permissible that p (not obligatory that not- p), and so $Lp \supset Mp$ will mean that whatever is obligatory is at least permissible. This interpretation of L is known as a deontic interpretation, and for that reason $Lp \supset Mp$ is often called D, and the system obtained by adding it to K as an extra axiom is known as the system D; that is, D is defined as K + D.

D: $Lp \supset Mp$

D is sound and complete with respect to the class of frames in which R is serial – for every $w \in W$, there is some w' , perhaps w itself, as in T, but perhaps not, such that wRw' .

In the early days of modal logic, disputes centered around the question of whether a given principle of modal logic was correct or not. Often these disputes involved formulae in which one modal operator occurs within the scope of another – formulae such as $Lp \supset LLp$. Sequences such as LL are known as iterated modalities, and it is tempting to consider the possibility that all iterated modalities might be equivalent to uniterated ones or to a small number of iterated ones. Consider the following:

(3) $Mp \equiv LMp$

(4) $Lp \equiv MLp$

(5) $Mp \equiv MMp$

(6) $Lp \equiv LLp$

None of these is a theorem even of T. Some of them can be derived from others. We can obtain (5) and (6) by adding $Lp \supset LLp$ to T; this system is known as the system S4. We can obtain all of (3)–(6) by adding $Mp \supset LMp$ to T; this system is known as the system S5. The names 'S4' and 'S5' derive from Lewis and Langford (1932: 501), in which systems deductively equivalent to these are the fourth and fifth in a series of modal systems. These systems too can be studied semantically. Suppose that R is required to be

transitive; that is, suppose that, for any worlds w_1 , w_2 , and w_3 , if w_1Rw_2 and w_2Rw_3 then w_1Rw_3 . If so, then $Lp \supset LLp$ will be valid, but if nontransitive frames are permitted it need not be. S4 is sound and complete with respect to all reflexive and transitive frames. Suppose that in addition R is symmetrical, that is, if wRw' then $w'Rw$. S5 is sound and complete with respect to all reflexive, transitive, and symmetrical frames.

Not all normal modal logics are so well-behaved, however. There exist systems that can be proved to be incomplete in the sense that there is **no** class of frames such that their theorems are precisely the wff that are valid on every frame in the class. One simple example is the system $KH = K + H$.

H: $L(Lp \equiv p) \supset Lp$

Every frame for H also validates $Lp \supset LLp$, but $Lp \supset LLp$ is not a theorem of KH. The incompleteness of this system is proved in Boolos and Sambin (1985). A simplified proof appears in Hughes and Cresswell (1996: Chap. 9). Much current research in propositional modal logic is devoted to the systematic study of large families of logics to examine the conditions under which they have, or lack, properties such as these.

Modal logic can be given a temporal interpretation. The propositional logic of linear time in which L means 'it is and always will be that ...' is called S4.3; it is S4 together with **D1**.

D1: $L(Lp \supset q) \vee L(Lq \supset p)$

The logic of discrete time, in which each moment has a unique successor, S4.3.1, is S4.3 + **N1**.

N1: $L(Lp \supset Lp) \supset p \supset (MLp \supset Lp)$

This logic has a venerable history. In 1957, Arthur Prior conjectured that S4 was the logic of time with this structure, but later authors proved it to be S4.3.1. Prior's name for this was D (for Diodorus Cronos, not to be confused with D for the deontic system). The history is told in Prior (1967: Chap. 2). Another logic with a philosophical and mathematical interest is one variously called KW or G. It is K together with **W**.

W: $L(Lp \supset p) \supset Lp$

One of its interpretations is that it expresses the logic of provability – with L meaning, 'it is provable that'. From a purely modal point of view, it is sound and complete with respect to the class of all finite frames in which R is transitive and asymmetrical. The name W is from Segerberg (1971: 84); it is called G in Boolos (1979). For a more recent survey of the history of provability logic, see Boolos and Sambin (1990). The system dates at least from Löb (1966).

An important modal notion is that of entailment. By this we understand the converse of the relation of following logically from (when this is understood as a relation between propositions, not wff); that is, to say that a proposition, p , entails a proposition, q , is simply an alternative way of saying that q follows logically from p or that the inference from p to q is logically valid. In modal logic, we can say that p entails q iff $L(p \supset q)$. But then we are faced with the following valid wff.

(7) $L((p \wedge \sim p) \supset q)$

(8) $L((q \supset (p \vee \sim p))$

With this interpretation, (7) means that any proposition of the form $(p \wedge \sim p)$ entails any proposition whatever, and (8) means that any proposition whatever entails any proposition of the form $(p \vee \sim p)$. Although this may seem strange, those who wish to reject either (7) or (8) have to face the following argument. The following principles seem intuitively to be valid:

1. Any conjunction entails each of its conjuncts.
2. Any proposition, p , entails $(p \vee q)$, no matter what q may be.
3. The premises $(p \vee q)$ and $\sim p$ together entail the conclusion q (the principle of the disjunctive syllogism).
4. Whenever p entails q and q entails r , then p entails r (the principle of the transitivity of entailment).

Lewis showed long ago (Lewis and Langford, 1932: 250–251) that by using these principles we can always derive any arbitrary proposition, q , from any proposition of the form $(p \wedge \sim p)$, as shown in Table 2. This derivation shows that the price that has to be paid for denying that $(p \wedge \sim p)$ entails q is the abandonment of at least one of the principles 1–4. The most fully developed formal response to these paradoxes consists of abandoning principle 3, the principle of disjunctive syllogism. Logics that do this are called relevance logics. A survey of relevance logic is found in Dunn (1986) and Mares and Meyer (2001).

Table 2 Derivation of propositions using the four principles

Principle	Proposition
	(i) $p \wedge \sim p$
From (i), by A	(ii) p
From (ii), by B	(iii) $p \vee q$
From (i), by A	(iv) $\sim p$
From (iii) and (iv), by C	(v) q
So by D , $(p \wedge \sim p)$ entails q	

First-order predicate logic can also be extended by the addition of modal operators. (For more details of modal predicate logic see Hughes and Cresswell, 1996: pt. 3; Garson, 1984.) The most interesting consequences of such extensions are those that affect mixed principles, principles that relate quantifiers and modal operators and that cannot be stated at the level of modal propositional logic or nonmodal predicate logic. Thus, (9) is valid, but (10) is not.

$$(9) \exists xL\alpha \supset L\exists x\alpha$$

$$(10) L\exists x\alpha \supset \exists xL\alpha$$

(Even if a game must have a winner there need be no one who must win.) In some cases the principles of the extended system will depend on the propositional logic on which it is based. An example is a formula studied by Ruth Barcan Marcus, who first considered combining modal logic with first-order predicate logic and introduced the formula in Barcan (1946). The Barcan formula (BF) is:

$$\forall xL\alpha \supset L\forall x\alpha$$

which is provable in some modal systems but not in others. If both directions are assumed, so that we have $\forall xL\alpha \equiv L\forall x\alpha$, then this formula expresses the principle that the domain of individuals is held constant over all possible worlds. A temporal version of the Barcan formula might make its interpretation clearer. Let us assume that everyone now in existence will die before 2154. Then, if L means 'it will always be the case that' and α is the wff 'x dies before 2154', then $\forall xL\alpha$ is true. But it is not at all likely that it will always be the case that everyone will die before 2154 because people who do not now exist may well live beyond then, and so $L\forall x\alpha$ will be false. This assumes that a quantifier only ranges over the individuals that exist at the time or in the world at which the wff is being evaluated, but indicates why BF has been a matter of controversy.

It is possible to have complete predicate logics whose predicate extensions are incomplete. One such is S4.2, which is S4 + G1.

$$\text{G1: } MLp \supset LMp$$

S4.2 is characterized by frames that are reflexive, transitive, and convergent, in the sense that, if a world w_1 can see two worlds w_2 and w_3 then there is a world w_4 that both w_2 and w_3 can see. But the predicate extension of S4.2 + BF is not characterized by any class of frames. Perhaps more interesting is the case of the systems S4.3.1 and KW (or G) previously mentioned, the logics of discrete time and of provability. It is established in Cresswell (1997) that the predicate logic characterized by all frames for these

systems is not recursively axiomatizable because they, together with a whole family of systems containing N1 and $Lp \supset LLp$, when combined with first-order logic, enable the expression of second-order arithmetic.

When identity is added, even more questions arise. The usual axioms for identity easily allow the derivation of LI:

$$(x = y) \supset L(x = y)$$

but should we really say that all identities are necessary? Take:

$$(11) \text{ the composer of 'Threnody for Mrs S' = the composer of 'Salm'}$$

An important feature of (11) is that it uses the phrases *the composer of 'Threnody for Mrs S'* and *the composer of 'Salm'*. Such phrases are often called definite descriptions, and they pose problems even in nonmodal predicate logic. One of the first to see this was Bertrand Russell, whose celebrated example was

$$(12) \text{ the present king of France is bald}$$

Because there is no present king of France, it would seem that (12) is false. But then it would seem that (13) is true.

$$(13) \text{ the present king of France is not bald}$$

But (13) does not seem true either, for the same reason as (12). Even worse is sentence (14).

$$(14) \text{ the present king of France does not exist}$$

Russell claimed that the phrase *the present king of France* does not function like a name at all, and his account of the matter can help with (11). If we follow Russell, (11) makes five claims:

1. At least one person composed 'Threnody for Mrs S.'
2. At most one person composed 'Threnody for Mrs S.'
3. At least one person composed 'Salm.'
4. At most one person composed 'Salm.'
5. $\forall x\forall y((x \text{ composed 'Threnody for Mrs S' } \wedge y \text{ composed 'Salm'}) \supset x = y)$.

Look carefully at claim 5. This claim is true but not necessarily true, so putting L in front of it gives us a false sentence. But LI does not license us to put L in front of claim 5. What LI does allow is for us to move from claim 5 to claim 6.

6. $\forall x\forall y((x \text{ composed 'Threnody for Mrs S' } \wedge y \text{ composed 'Salm'}) \supset L(x = y))$.

And it is less clear that claim 6 is at all objectionable.

Suppose, nevertheless, that we still wish to abandon LI. To falsify LI, we let the values of the variables be strings of objects that may coincide in some worlds but not in others. In the present example, letting x mean 'The composer of "Threnody for Mrs S"' would mean requiring its value in a world w be whoever in w composed 'Threnody for Mrs S,' while y could stand for whoever composed 'Salm' in w . But there is a problem. Allowing all such strings would make the wff (10) valid, and it was remarked that (10) could be false in a game in which it is necessary that some player will win, although there is no individual player who is bound to win. There is, however, one way in which we could make (10) sound plausible. Consider, for example, the expression *the governor-general of New Zealand*, as it may occur in a constitutional context. The law may specify that at a certain point the signature of the governor-general is required before an act of parliament becomes law; yet on one occasion the governor-general may be Michael Hardie-Boys and on another it may be Sylvia Cartwright. Thus, the phrase *the governor-general of New Zealand* does not designate any particular individual (as an assemblage of flesh and blood); yet we can in a sense think of it as standing for a single object, contrasted with *the prime minister* and so forth.

Such objects are often called intensional objects or individual concepts. In a logic in which the individual variables range over all intensional objects, (10) would be valid because, if it must be the case that there is someone who must sign acts into law, then although no individual person must be that someone, yet there is someone (viz. the governor-general) whose signature is required. An adequate semantics for the contingent identity systems that do not validate (10) would therefore have to place restrictions on allowable strings of objects and neither require that only strings consisting of the same member of D in each world should count as objects—for that would validate LI – nor that any string whatever of members of D should count as an object – for that would validate (10).

All the systems of modal logic considered so far have assumed a single necessity operator, with its possibility dual. An important class of systems with more than one is the class of tense logics. (For a survey see Prior, 1967.) A tense logic has two operators, L_1 and L_2 , where L_1 means 'it always will be the case that' and L_2 means 'it always has been the case that'. In frames for a tense logic, the associated relations R_1 and R_2 are so related that one is the converse of the other, that is, wR_1w' iff $w'R_2w$. Another way of introducing families of modal operators is suggested by a possible interpretation of modal logic in computer science. In this interpretation, the worlds are states

in the running of a program. If π is a computer program, then $[\pi]\alpha$ means that, after program π has been run, α will be true. If w is any world, then $wR_\pi w'$ means that state w' results from the running of program π . This interpretation of modal logic is called dynamic logic. What gives dynamic logic its interest is the possibility of combining simple programs to get more complex ones. Thus, if π_1 and π_2 are two programs, then the expression $\pi_1;\pi_2$ refers to the program 'first do π_1 and then do π_2 ', and $[\pi_1;\pi_2]\alpha$ means that α will be true if this is done. The relation corresponding to $[\pi_1;\pi_2]$ may be defined to hold between w and w' iff $\exists u(wR_{\pi_1}u \wedge uR_{\pi_2}w')$. Other computing operations can generate similar modal operators, with appropriate conditions on their accessibility relations (see Goldblatt, 1987: Chap. 10). It is also possible to develop dynamic predicate logic. For an introductory survey, see Goldblatt (1987: pt. 3).

The most general kind of possible-worlds semantics for propositional operators is based on that idea of the truth set of a formula. In any model, we can define $|x|$ as $\{w \in W: V(x,w) = 1\}$. In evaluating Lx in a world w , all the input that we require is to know which set of worlds forms the truth set of x . Whatever L means, what it has to do is to declare Lx true at w for some truth sets and false for others. So the meaning of L must specify which sets of worlds form acceptable truth sets in world w . These sets of worlds are called the neighborhoods of w , and a neighborhood frame for a language of modal propositional logic is a pair $\langle W, R \rangle$ in which W is a set (of worlds) and R is a neighborhood relation. (For some remarks on the history of neighborhood semantics, see Segerberg, 1971: 72.) A neighborhood relation is a relation between a world w and a subset A of W , and A is a neighborhood of w iff wRA . We then say that $V(Lx,w) = 1$ iff $wR|x|$. A frame of the kind assumed earlier, in which R is a relation between worlds, is often called a relational frame, and it is not difficult to see that every relational frame is a special case of a neighborhood frame. To be precise, a relational frame is a neighborhood frame in which for every $w \in W$ there is a set B of those and only those worlds that are accessible to w (i.e., B is the set of worlds w can 'see') and wRA iff $B \subseteq A$. What this means is that x 's truth set is a neighborhood of w iff it contains all the worlds accessible from w , which is of course precisely what the truth of Lx in a relational frame amounts to.

Neighborhood semantics can be devised for systems with operators taking more than one argument. A philosophically important example here is the logic of counterfactuals as developed in the late 1960s and early 1970s. We present here a version of the semantics found in Lewis (1973), but the same idea is also

found in Stalnaker (1968) and Åqvist (1973). Counterfactual logic is based on a dyadic operator $\Box \rightarrow$, where $\alpha \Box \rightarrow \beta$ means that ‘if α were to be the case then β would be the case’. Lewis’s idea is that, given a possible world w , some worlds are closer to w than others. If we write $w' <_w w''$ to mean that ‘ w' is closer to w than w'' is’, then the semantics for $\Box \rightarrow$ will be that $\alpha \Box \rightarrow \beta$ is true in w iff either α is not true at any world or there is a world w' at which α and β are both true that is closer to w than any world w'' at which α is true but β is not. A counterfactual frame can be described as a neighborhood frame in the following way. Because $\Box \rightarrow$ is dyadic, its neighborhood relation R will relate worlds to pairs $\langle A, B \rangle$ where $A \subseteq W$ and $B \subseteq W$. The standard rule for a dyadic operator δ using an associated neighborhood relation R is (15).

$$(15) \quad V(\delta\alpha\beta, w) = 1 \text{ iff } wR\langle\alpha, \beta\rangle$$

A frame $\langle W, R \rangle$ will be a counterfactual frame iff it is based on a nearness relation $<$ in such a way that $wR\langle A, B \rangle$ iff either (16) or (17).

$$(16) \quad A = \emptyset$$

$$(17) \quad \text{There is some } w' \text{ such that } w' \in A \cap B \text{ and for every } w'', \text{ if } w'' \in A \cap \neg B \text{ then } w' <_w w''$$

Which counterfactual logic we get will depend on what kind of conditions we put on $<$. For instance, under the plausible assumption that the closest world to w is w itself, we get a frame that validates the wff in (18).

$$(18) \quad p \supset ((p \Box \rightarrow q) \equiv q)$$

By contrast, on any plausible account of nearness, many wff that are valid for \supset fail for $\Box \rightarrow$. For instance in standard systems of counterfactual logic, neither (19) nor (20) is valid.

$$(19) \quad ((p \Box \rightarrow q) \wedge (q \Box \rightarrow r)) \supset (p \Box \rightarrow r)$$

$$(20) \quad (p \Box \rightarrow q) \supset (\sim q \Box \rightarrow \sim p)$$

Questions such as these bring us to the boundary between modal logic, metaphysics, and semantics and remind us of the rich potential that the theory of possible worlds has for illuminating such issues. The possible-worlds semantics can be generalized to deal with any operators whose meanings are operations on propositions as sets of possible worlds and form a congenial tool for those who think that the meaning of a sentence is its truth conditions and that these be taken literally as a set of possible worlds – the worlds in which the sentence is true.

Further information on modal logic, including more detailed bibliographical references, may be found in a number of works. See, for instance, Blackburn *et al.*

(2001), Bull and Segerberg (1984), Chargrov and Zaharyashev (1997), Chellas (1980), and Hughes and Cresswell (1996).

Modern Linguistics: 1800 to the Present Day

R Harris, Oxford, UK

Introduction

It is during the course of the 19th century that we first find linguists self-consciously making statements about the history of their own discipline. The very fact that they do so is part of the *prima facie* evidence for the existence of that discipline (as indeed it was intended to be). For, it need hardly be said, their main concern was not so much to establish what had happened in the past as to establish the contemporary

autonomy of their own branch of inquiry. For this purpose they usually adopted a familiar “torch of learning” model, in which knowledge is passed on from one age to the next. As successive generations fan the sacred Flame with their own contribution, it burns ever brighter. The current torch-holder often turns out to be the scholar telling the story, or a close colleague.

This pattern of historical self-justification has been repeated more or less without interruption in linguistics from 1800 down to the present day, beginning with the Comparative Philologists and continuing with the Neogrammarians. A classic case

from the early 20th century is the introductory chapter in F. de Saussure's *Cours de linguistique générale* (1916), which itself recruits the Comparative Philologists and the Neogrammarians as honorable predecessors. Another is chapters 1–4 of *Language: its nature, development and origin* (Jespersen, 1922). A third is chapter 1 of *Language* (Bloomfield, 1933). A fourth and even more blatant example (if that were possible) is *Linguistics* (Fries, 1966), which leads up to what Fries calls triumphantly “the breakthrough” of American structural linguistics and the arrival of transformational-generative grammar. Endemic to this self-justificatory pattern is the notion that one's predecessors, although great scholars, never quite got it right (or even, occasionally, got it wrong, thus all but extinguishing the Flame).

Underlying most of these self-justificatory historical accounts lies a concern to show that linguistics is – or at last has now, i.e., in the author's own generation, become – a ‘science.’ This anxiety is bound up with the whole question of the academic prestige of ‘the sciences’ as developed in 19th- and 20th-century universities in Europe, and the diminishing prestige of ‘the arts.’ ‘Science’ was from the beginning a watchword or slogan that modern linguistics appropriated as its own, thus implicitly distinguishing the subject from all ‘pre-scientific’ studies of language and languages. It is emphatically reaffirmed in the glossary to the first edition of this encyclopedia, which contains the blunt propagandist equation “linguistic science = linguistics” (Asher, 1994).

The brief account that follows describes the main phases usually identified in this self-serving tradition of historiography. It makes no attempt to list all the individual ‘schools’ and ‘movements’ that have contributed to modern linguistics, let alone all the eminent scholars. Nor does it cover ‘applied’ linguistics in such diverse areas as language acquisition, language pathology, language planning, language teaching, and psycholinguistics.

Comparative Philology

Modern linguistics is usually portrayed as arising out of a preceding inquiry called Comparative Philology or Comparative Grammar. The Comparativists were already anxious to distinguish themselves from an earlier scholarly tradition that they often referred to as Classical Philology. Adopting a “torch of learning” model requires an identification of some person or persons who first lit the torch. That role was retrospectively thrust, by the Comparativists and their successors, upon Sir William Jones (1746–1794).

According to later scholars seeking to validate their version of the history of linguistics, the stimulus that

Jones provided to 19th-century developments was ‘immense’ (Robins, 1994). But this overenthusiastic claim is based mainly on the endless quotation of one paragraph from a single lecture that Jones gave in India to the Asiatic Society in 1786. There he proposed that Sanskrit, Greek, and Latin were languages that might be derived from “some common source, which, perhaps, no longer exists.” He also suggested in the same paragraph that Gothic, Celtic, and Old Persian might have belonged to the same family.

On this flimsy evidence, Jones could hardly have anticipated that later generations would hail him as a ‘founder’ of Comparative Philology, much less as ‘the first modern linguist.’ Jones was a newly arrived British judge sent out from London to administer colonial justice in India. What he saw was the practical advantage of having at his disposal a digest of Hindu and Islamic law. For this purpose, a knowledge of Sanskrit was essential, and he applied himself to it. The irony is that Jones himself had no great regard for philological studies as such. As far as he was concerned, languages were “mere instruments of real learning.” They were not objects of study in their own right.

But that, precisely, was the central notion of the Comparativists. In their view, languages were in themselves organic growths, developing in accordance with their own organic nature, and therefore qualifying as raw ‘materials’ for a modern science of language. On this basis, as F. M. Müller (1823–1900), first professor of Comparative Philology at Oxford, insisted, it was possible to envisage the study of languages as comparable to such natural sciences as biology and astronomy. But no such project was further from the mind of Jones.

The scholars who, in practice, set up Comparative Philology as an academic discipline were J. Grimm (1785–1863), R. Rask (1787–1832), and F. Bopp (1791–1867). Their work had as its focus the comparative study of the Indo-European languages. They were not engaged in what later came to be known as ‘general linguistics,’ except insofar as their methods and arguments presupposed certain assumptions about the ‘nature’ of language. One of their preoccupations was the historical task of ‘reconstructing’ the unattested ancestral language from which, they assumed, all Indo-European languages had sprung. In this respect, they placed previously inchoate discussions of linguistic origins on a new footing.

The Neogrammarians

The Neogrammarians are seen as marking an ‘advance’ on Comparative Philology, inasmuch as

they endeavored, in the mid 19th century, to establish 'laws' of linguistic development. Discovering 'laws' was then regarded as a *sine qua non* for setting up a 'science.' The principal figures in the Neogrammarian (*Junggrammatiker*) movement were acknowledged to be H. Osthoff (1847–1909), K. Brugmann (1849–1919), A. Leskien (1840–1916), and H. Paul (1846–1921). Their main claim to fame was their formulation of the principle that the 'laws' of sound change hold without exception. Thus if, for example, an intervocalic stop consonant becomes a fricative in one word, this is predicted to happen in all such words when that sound occurs in a similar environment in the same language. In this respect, the Neogrammarians supposedly brought linguistics in line with the 19th-century conception of the natural sciences. Osthoff spoke of the "blind necessity" with which sound laws operate. (Cf. the Newtonian law of gravitation.) The claim itself is virtually worthless, since any instance of an exception could always, for the Neogrammarians, be accommodated by *ad hoc* modification of the 'law' in question. We end up with mere statements of what has been observed to happen with regularity in the past. The exceptionless laws are no more than products of their own hind-sighted formulation.

Saussurean Structuralism

Although F. de Saussure (1857–1913) paid great respect to the Neogrammarians, his approach opened up a quite different chapter in academic language studies. The posthumously published *Cours de linguistique générale* (1916), based on lecture notes taken by his students at the University of Geneva, came to be regarded as the Magna Carta of modern linguistics. In this work, linguistics is presented as one branch of a more all-embracing study of signs, which Saussure referred to as 'semiology' (*sémiologie*).

Saussure did not believe in linguistic 'laws.' He saw 19th-century 'historical' linguistics as a muddle and thought that the Neogrammarians offered no insight at all into what a language was for its speakers. He accordingly drew a fundamental distinction between 'synchronic' and 'diachronic' linguistics. Synchrony is often equated, but mistakenly, with a study of the present-day language. Nor is Saussure's *linguistique diachronique* a synonym for *linguistique historique*, as will be evident to anyone who reads attentively the section on that subject in the *Cours de linguistique générale*. But it was often misunderstood by later linguistic theorists.

Saussure did not mount an all-out attack on comparative and historical linguistics, but he shunted those inquiries into an intellectual siding from which

they could make no effective contribution to answering the main questions that linguistic theory had to tackle.

For Saussure, *linguistique diachronique* was an academic edifice set up by the linguist, with a perspective altogether different from that available to the individual member of a linguistic community at any one time. *Linguistique synchronique*, on the other hand, was an attempt to capture the psychological reality underlying the way a typical member of the linguistic community uses its communal language. This distinction was, and always will be, controversial. Saussure himself did not help matters by sometimes appearing to identify the synchronic viewpoint with that of the traditional (prescriptive) grammarian.

Saussure's distinction between *langue* (the collective language system) and *parole* (the linguistic act of the individual) also remained a bone of contention. Although Saussure neither coined nor used the term "structuralism," this was the label later attached to his conception of synchronic analysis. Its principal feature is that forms and meanings are not to be identified by matching them with anything external to language (e.g., sounds or physical objects), but solely by reference to internal (structural) contrasts arising within the language itself. Thus, for example, the form of the English word /bat/ cannot be stated in terms of the sequence of sounds [bat] but only by listing the contrasts that distinguish this word from /kat/, /fat/, /hat/, etc. This, for Saussure, is a necessary consequence of realizing that different languages operate with different sets of phonological contrasts: there is no fixed and finite set of phonemes valid for all languages. Similarly, the meaning of a word like *horse* cannot be stated by identifying a certain species of animal and saying that *horse* is the name of this species. Why not? Because different languages recognize different biological species. Thus Saussure's view of meaning departed radically both from traditional lexicography and from that of the founder of modern semantics, his older contemporary M. Bréal (1832–1915). Saussure rejects the entire nomenclaturist approach to language entrenched in the Western tradition. It follows from this that all languages are irreducibly different. They are not just alternative ways of expressing some universal set of concepts, as Aristotle and many others had supposed.

By adopting this uncompromisingly holistic approach to linguistic analysis, Saussure in effect pulled the theoretical rug from under both Comparative Philology and historical linguistics as practiced by the Neogrammarians. His ideas were taken up and developed, particularly in Europe, by the so-called Prague school of linguistics. Two of its leading members were

N. Trubetzkoy (1890–1938), whose work on phonology became highly influential, and R. Jakobson (1896–1983). Another branch of structural linguistics emerged in Denmark as ‘glossematics,’ whose leading exponent was the Danish linguist L. Hjelmslev (1899–1965). In France, G. Guillaume (1883–1960) was responsible for a highly original exploration of – and reaction against – some Saussurean ideas, in propounding what he called the ‘psychomechanics’ of language.

During Saussure’s lifetime, two other approaches – linguistic geography and linguistic anthropology – came to prominence in language studies.

Linguistic Geography

In Europe, dialectologists began the task of documenting current linguistic usage and the geographical distribution of linguistic features. This led to the compilation of the first linguistic ‘atlases.’ The earliest (1881) was that of the German dialectologist G. Wenker, who sent questionnaires to 30,000 German schoolteachers in an attempt to survey features of local pronunciation. A Romanian linguistic atlas was published by G. Weigand in 1909, compiled on the basis of direct interviews with informants. In France, J. Gilliéron and E. Edmont published (1902–1910) a linguistic atlas based on interviews carried out at more than 600 localities. All this early work was done without the benefit of sound-recording apparatus and thus depended very much on the linguist’s ear and the transcription system used. From it emerged, however, one new (and controversial) theoretical concept: the ‘isogloss.’ Isoglosses were lines drawn on a map, demarcating areas in which a particular feature occurred and separating those from areas of non-occurrence. The study of isoglosses in turn gave rise to controversial conclusions concerning the existence of ‘dialects,’ which, according to some investigators, proved to be illusory.

J. Gilliéron (1854–1926), on the basis of his cartographical studies, pronounced the ‘bankruptcy’ of traditional etymology and reached the famous conclusion that “each word has its own history.” When this conclusion is combined with doubt about the existence of dialects, it leads directly to doubt about the existences of ‘languages’ too.

Linguistic Anthropology

In America during the same period, anthropologists provided a significant input to language studies, in particular under the auspices of the Bureau of American Ethnology. Attention focused upon the description and classification of native Amerindian

(i.e., non-Indo-European) languages – a source of material unavailable in Europe. The study of these languages was also in part motivated by missionary activities and Bible translation – enterprises that played no comparable role in Europe. As early as 1838, the French scholar P. E. Duponceau (1760–1844) argued that all Amerindian languages had a basic grammatical structure unknown in the Indo-European family, and popularized the term ‘polysynthetic’ to identify it. In 19th-century language typologies, polysynthetic languages were often distinguished from ‘synthetic’ and ‘analytic’ languages. The characteristic of polysynthetic languages was said to be a tendency to prefer long, complex words that ‘incorporate’ a variety of grammatical distinctions. Thus, for example, in Eskimo a single word expresses the idea that might be rendered in English by the sentence “Do you think he really intends to go to look after it?” (The term ‘incorporating’ is also used to describe this type of structure.)

One result of this American anthropological tradition of language study was the publication of the *Handbook of American Indian languages* (1911–1922). The team responsible for this was led by F. Boas (1858–1942), a German scholar who had emigrated to the United States. The *Handbook* comprised brief descriptive accounts of the phonetics, grammar, and vocabulary of a range of Amerindian languages. Boas himself rejected the view that all Amerindian languages were ‘polysynthetic.’ His most important theoretical contribution to general linguistics is sometimes said to be his observation that Europeans were prone to misdescribe the sounds of Amerindian languages, because they could not avoid hearing them through the grid imposed by the phonetics of the European languages they themselves spoke. This idea has obvious links to Saussure’s insistence that every language is structurally unique, although Boas arrived at this notion independently of Saussure.

In Europe, the chief influence of anthropology on the development of linguistics is to be seen in the work of the Polish anthropologist B. K. Malinowski (1884–1942), whose fieldwork in the Trobriand Islands inspired his view of language. Malinowski popularized the notion of “phatic communion,” which, in contrast to the traditional idea that language existed to communicate ‘thoughts,’ emphasized the role of language as a mode of action for establishing social bonds.

Malinowski’s ideas were taken up by J. R. Firth (1890–1960), professor of general linguistics at London University, whose ideas were in turn developed by ‘neo-Firthians,’ such as M. A. K. Halliday (b. 1925). Firth’s ‘polysystemic’ linguistics emphasized the need for linguists to set up different ‘systems’

in order to describe relations between linguistic units at different 'levels.' Firth viewed linguistics as language "turned back upon itself." He is sometimes regarded as the archetypal 'hocus-pocus' linguist, for whom linguistics is a verbal game played in accordance with metalinguistic rules devised by the linguist (as distinct from 'God's-truth' linguists, who view their task as being to discover some external linguistic reality that exists independently of their inquiries).

Linguistic Relativity

Another line of thinking in which Saussurean ideas link up with those emanating from the American anthropological tradition of language study concerns the theory that came to be known as 'linguistic relativity' or 'linguistic relativism.' It is also known as the 'Sapir-Whorf hypothesis,' of which there are various versions.

The term *relativity* is often taken as alluding to the work of A. Einstein (1879–1955) in physics. In one sense, this is not misguided, inasmuch as Einsteinian relativity emphasized the dependence of 'facts' on the viewpoint of the observer. The Sapir-Whorf hypothesis does likewise. Einstein himself, however, was far from being a linguistic relativist. Another figure often invoked in connection with the Sapir-Whorf hypothesis is the German polymath W. von Humboldt (1767–1835), whose ideas are seen as anticipating the hypothesis, in that he associated each national language with a distinctive way of viewing the world.

E. Sapir (1884–1939) was a student of Boas's and published a study of Takelma in the *Handbook of American Indian languages*. B. L. Whorf (1897–1941) worked for the Hartford Fire Insurance Company and became a student of Sapir's at Yale. In his insurance work, Whorf was struck by the fact that accidents were often caused by the way things and situations were described. (For example, an oil drum described as 'empty' had actually been full of highly dangerous vapor.) In its most general version, the Sapir-Whorf hypothesis claims that the language we speak provides a linguistic lens through which we view the world. It follows from this that speakers of different languages see the world – and interpret their own experience of it – in different, incommensurable ways.

This is probably the most revolutionary idea to emerge from modern linguistics – revolutionary in the sense that it overturns the assumptions underlying the development of language studies throughout the Western tradition. It also has far-reaching implications for linguistic epistemology. These implications tend to be ignored in mainstream linguistics, because they subvert the whole basis of establishing linguistics

as a 'science.' Insofar as mainstream linguistics has an answer to the problems raised by the Sapir-Whorf hypothesis, it lies in mounting a rival hypothesis claiming that there exists at some 'deep' level in human psychology a universal grammar common to all languages (Chomsky, 1986). It is difficult to see how this conflict of views could ever be resolved by the adduction of empirical linguistic 'evidence.' The debate is ultimately sterile. Both the Sapir-Whorf hypothesis and the universal grammar hypothesis open up routes that lead linguistics nowhere. That has not prevented partisans on both sides from devoting much time and effort to driving their own hypothesis further into no-man's-land.

Behaviorism

In America Saussure's work remained for some time without noticeable influence, in part because Saussurean linguistics eventually found itself under attack from psychologists, and in particular from linguists who had adopted the psychological doctrines of behaviorism. The leading linguistic exponent of these views between World War I and World War II was L. Bloomfield (1887–1949).

Although Bloomfield had himself studied Amerindian languages, and early in his career had been attracted to the psychological theories of Wundt, he was 'converted' to behaviorism at Ohio State University by A. P. Weiss (1879–1931). Bloomfield said of Weiss that he "was not a student of language, but he was probably the first man to see its significance" – an astonishing statement and an astonishing tribute. From the time of his acquaintance with Weiss, Bloomfield became increasingly and implacably opposed to 'mentalism' in linguistics. This entailed a rejection of Saussurean linguistics, given Saussure's view of the linguistic sign as a purely psychological unit existing in the human mind as a pairing of form (*signifiant*) with meaning (*signifié*). Somewhat more equivocal was Bloomfield's attitude to Boas's notion that linguistic structure lay below the level of human consciousness. Boas's introductory essay to the *Handbook of American Indian languages* had contained a concluding section on the "Unconscious Character of Linguistic Phenomena."

In accordance with behaviorist precepts, Bloomfield set out to banish from 'scientific' linguistics all appeal to unobservables. This meant no great loss as far as sound was concerned, since speech was audible and recordable. The problem lay with meaning. If meaning were in the mind of the speaker, they were unobservable and unrecordable. Accordingly, Bloomfield had to fall back on the ancient reocentrism of the Western tradition and declare that, for instance,

the meaning of the word *salt* is nothing other than the physical substance salt. Thus meaning was rescued and brought within the domain of linguistic observation. The question then arose, however, 'What is salt?' Recognizing that linguists could not be expected to be omniscient, Bloomfield's answer was that meanings could not be stated precisely except in domains where science had 'determined' the nature of the thing in question. Thus science had determined that salt in the physical world is sodium chloride. So the semantics of words for substances like salt posed no problem. But science had not yet determined what items in the 'real world,' if any, corresponded to such words as *love* and *hate*. There, according to Bloomfield, semantics would have to wait until scientists had got round to investigating such matters. So semantics was "the weak point in language-study" and was likely to remain so "until human knowledge advances very far beyond its present state" (Bloomfield, 1933).

The effect of this behaviorist doctrine was to skew linguistic inquiry in the direction of phonetics, since so much of semantics lay in the limbo of the unknown or unknowable.

Distributionalism

Some of Bloomfield's followers drew the conclusion that a 'science' of language was possible only if it ignored the analysis of meanings and concentrated solely on the analysis of linguistic forms. The attempt to theorize this nonsemantic approach to linguistic structure came to be regarded as characteristic of American (as opposed to Saussurean) 'structuralism.' Saussure would have regarded any such development as retrograde, rather than as an advance in the science of linguistics. In effect, it was a reversion to Greek atomism, although few if any of the American linguists involved were sufficiently well educated in the Classics to see the connection. Be that as it may, the outcome was a profound and misleading difference between the terms *structural* and *structuralism* as used in linguistics on either side of the Atlantic. Thus, for example, *Structural linguistics* (Harris, 1951) was the title of a well-known American textbook that (deliberately) excluded any consideration of linguistic meaning.

For the distributionalists, linguistic description consisted in identifying phonological units and defining all higher-order complexes by reference to the distribution of the basic units already defined. They assumed this could be done 'formally' – that is, without appealing at any stage to the supposed meaning of the items under investigation. The doyen of distributional linguistics was Z. S. Harris (1909–1992), whose critics argued that distributional analysis,

contrary to its proclaimed principles, tacitly took meaning into consideration at every turn. In other words – so the argument went – the linguist's task of determining whether two sounds were the same or different was impossible without information about whether the native speaker treated them as articulating a minimal semantic distinction.

Distributionalism was 'formalist' in another sense. It reduced the definition of linguistic units to the sum total of analytic procedures involved in identifying them. Adoption of a different set of procedures might produce a different set of units. This in turn had implications for the status of linguistics as a 'science.' (The assumption was that 'scientific' knowledge should not be at the mercy of the methodological preferences of the scientist.)

However, at a deeper level, distributionalism also connected with the revolution in the epistemology of science associated with Einsteinian relativity. In particular, the theory of operationalism in physics, as advanced by P. W. Bridgman (1882–1962), could be seen as a counterpart to Harris's distributionalism in linguistics. For Bridgman, all physical concepts were defined ultimately by reference to the techniques of measurement deployed in any scientific observation.

Generativism

One of Harris's students, A. N. Chomsky (b. 1929), proposed a novel approach to linguistic analysis by borrowing an idea from mathematical logic. It is possible to define a formal logistic system by setting out a string of 'rules' or algorithms that constrain transformations from one sequence of symbols to another. Chomsky saw that this procedure could be applied *in extenso* to the description of languages like English, if it were possible to propose a nucleus of symbols and transformational rules that would eventually 'generate' all and only the sentences of English. Many years of work were devoted to this Herculean quasi-mathematical labor, which never came to completion, either for English or for any other language.

Chomsky attacked behavioristic approaches to language, in particular the explanations offered by the experimental psychologist B. F. Skinner (1904–1990) concerning language acquisition. In the view of Chomsky and other generativists, language users were to be credited with reliable linguistic 'intuitions' as to the grammaticality or otherwise of expressions in their language. How these intuitions were to be distinguished from the products of teaching, rationalization, or personal preference was never clearly explained.

Although Chomsky at one point saw his project as a formalization of the Saussurean distinction between *langue* (= Chomskyan ‘competence’) and *parole* (= Chomskyan ‘performance’), that would have amused Saussure, for whom the naïve notion that a language could be reduced to a set of sentences was not even a starter. Generativism has been criticized by sociolinguists (see the next section) for ignoring linguistic variation and verbal interactions in ‘real-world’ contexts. In particular, Chomsky’s frequent appeal to an “ideal speaker-listener” is seen as an unacceptable evasion of linguistic issues that should be addressed empirically.

Sociolinguistics and Pragmatics

During the 20th century, there had also emerged in linguistics the simple but powerful idea that languages could be studied independently of any theory about “the language system.” So it did not matter too much what theorists like Saussure or Bloomfield or Chomsky said. Whatever they said, linguistic behavior was still available for description as a social phenomenon. This is the basic idea behind what came to be called ‘sociolinguistics.’

It derives from traditional dialectology, but it now incorporates the notion that linguistic variation has other than geographical parameters. In particular, it embraces the notion that there are discernible patterns of linguistic variation that depend on age, sex, education, social status, social occasion, professional occupation, and other factors. All these may intersect in numerous ways. It is the task of the sociolinguist to document, disentangle, and explicate these complex patterns.

A sociolinguistic approach leads on naturally to ‘pragmatics’ or ‘pragmalinguistics.’ This has now become a catch-all category embracing virtually all forms of linguistic variation or distinguishing characteristics that can be detected when language is used in a particular type of activity or communication situation.

The main objection that has been leveled against linguistic research of this kind is that it falls inevitably under the aegis or influence of sociology, and thus is led to adopt techniques of investigation and methods of classification that are approved in that discipline (in particular the adoption of certain social classifications and statistical assessments that may perhaps be inappropriate or misleading for linguistic purposes).

Speech-Act Theory

Pursuing a sociolinguistic approach to its logical conclusion, one is led to ask not “What are the

basic sound units of a language?”, nor “What are the basic grammatical units and constructions?”, but “What are the basic speech acts by which one human being communicates with another?” Curiously, this question had been more or less neglected in modern linguistics until it was raised in the neighboring discipline of philosophy. That it was raised at all is due largely to the Oxford philosopher J. L. Austin (1911–1960), whose work in turn owes much to the climate of inquiry created in philosophy of language and philosophy of mathematics by G. Frege (1848–1925), B. A. W. Russell (1872–1970), G. E. Moore (1873–1958), and L. Wittgenstein (1889–1951).

The title of Austin’s brief but highly influential book *How to do things with words* (1962) strongly suggests the pragmatic orientation of his thought. He realized that stating a fact (recognized in traditional grammar as the province of the indicative mood) was only one of many verbal activities it was possible to engage in, even though it was the activity that traditional philosophy valued and paid attention to above all others. This led Austin to ask what other types of act were available to the speaker or writer. He pointed out that saying “I apologize” is not a description of an apology but the execution or performance of the act in question. This simple observation had escaped all traditional grammarians, for whom *I apologize* is on a par with any other first-person present indicative active, such as *I walk*.

Austin’s initial exposition of the performative dimension in linguistic communication was followed up in work by J. Searle (b. 1932) and H. P. Grice (1913–1988). No comprehensive taxonomy of speech acts has been forthcoming. One reason alleged by critics of speech-act theory is that this is impossible, because speech-acts proliferate *ad infinitum*, depending on the criteria adopted for identifying them. Another, perhaps more damaging, criticism is that speech-act theory itself tacitly relies on accepting of the prior existence of a code (i.e., a language) by means of which the act is articulated. In other words, the speech-act theorist is led into complicity with the traditional assumptions of orthodox linguistics. Without these, the speech act cannot be identified or described.

Language Origins and Nonhuman Language

The ancient question of linguistic origins fell out of favor in the course of the 19th century. The Société de Linguistique, founded in Paris in 1866, expressly forbade the presentation of papers on the subject. The eminent American philologist W. D. Whitney

(1827–1894) dismissed all discussion of the origins of language as “mere windy talk.” Interest was renewed, however, in the 20th century, largely through research from two directions.

With the general acceptance of Darwin’s theory of evolution, it seemed likely to many that language itself had developed from more primitive forms of communication used by less advanced ancestors of the human race. On this view, it ought to be possible in principle to account for language as having evolved on the basis of natural selection.

Others thought it more probable that language was the result of a unique genetic mutation. Others again maintained the skepticism of the 19th century and insisted that, in the present state of knowledge, it is impossible to progress beyond speculation to ‘science.’ The debate continues (Botha, 2003).

In the study of animal behavior, much attention was paid in the second half of the 20th century to the possibility of teaching linguistic skills to other primates, particularly those genetically close to *Homo sapiens*. It was generally accepted that apes were, for physiological reasons, unlikely to be able to produce articulated speech. But there seemed no reason why they might not master a language of gestures. Some of these projects developed systems based on American Sign Language for the Deaf. In later experiments, computer-monitored keyboards were used, and apes proved adept at mastering them.

From the beginning, work in this area was controversial. Skeptics questioned whether the use made by apes of the signs taught to them by human instructors was genuinely ‘linguistic,’ as distinct from being merely ‘imitative.’ (Pigeons had been taught to ‘play ping-pong,’ or at least to go through the motions, but no one seriously supposed that the birds understood what they were doing – i.e., playing a game.) However, it subsequently emerged that bonobos not only could use signs regularly to communicate their own wants, but could understand spoken English of a certain degree of grammatical complexity (Savage-Rumbaugh *et al.*, 1998).

Retrospect

When one looks back at the ambitious academic program that Saussure (1916) first laid out for modern linguistics, it is interesting to note what progress has been made. The program had three objectives. There is still a long way to go in pursuing Saussure’s first goal of describing all known languages and recording their history. His second goal, of determining the forces operating permanently and universally in all languages, is no nearer to fulfillment, because of fundamental disagreement about the methods to be

pursued. His third goal, that of defining and delimiting linguistics itself, threatens to disappear as the boundaries separating linguistics from neighboring disciplines become increasingly porous. The real weakness in Saussure’s original program, as it now appears, was its failure to make provision for any study of the actual contexts in which linguistic communication is embedded. Such studies seem inevitably to involve trespassing on or borrowing from work done by specialists in adjacent fields. As a result, fewer and fewer linguists any longer believe in the autonomy of linguistics. It would be a more accurate reflection of current trends to say that across a wide spectrum of academic research in the humanities the importance of linguistic considerations is increasingly acknowledged, and the interdependence between verbal and nonverbal communication recognized.

Modularity

R Carston, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Here is a general characterization of the concept of a mental module: it is a department of the mind that is dedicated to a specific domain of content and is largely autonomous from other departments of the mind. Possible content domains are visual perception, language, arithmetic, music, spatial orientation, social relations, and scientific reasoning, each of which may itself be made up of more fine-grained domains.

Although domain specificity and autonomy are central to any notion of modularity, there are also important differences in the kinds of mental structure that may be referred to as modules. The main distinction is between (a) systems of mental representations and (b) computational mechanisms (see Samuels, 2000). Modules of the first sort are sometimes called 'information' modules, 'Chomskyan' modules (after Noam Chomsky, who proposed such a modular view of the human language capacity), or 'competence' modules. Modules of the second sort are computational devices, processing systems, or 'performance' modules. Of course, modular systems of both kinds often coexist. For instance, a modular system for performing arithmetic computations might call on a domain-specific system of arithmetic knowledge; similarly, a modular mechanism for comprehending language (a parser) might deploy the contents of a Chomskyan module of linguistic information (see Segal, 1996).

Chomskyan modules ('C-modules' hereafter) are domain-specific bodies of knowledge that underpin a cognitive capacity. In addition to the well-known case of linguistic knowledge (the phonological, syntactic, and semantic knowledge constituting an individual's language), plausible candidates for such competence modules are physical knowledge (knowledge of some of the properties of physical objects),

biological knowledge (knowledge of some of the properties of living things), psychological knowledge (knowledge of some of the properties of human minds), and mathematical knowledge (knowledge of counting and numerical quantities).

However, there are bodies of domain-specific knowledge that do not qualify as C-modules. Consider, for instance, a child's beliefs about Batman or an adult's knowledge of British history. To count as a C-module, a knowledge system must meet two additional constraints. First, there must be restrictions on information flow (both the accessibility of the system's knowledge to other content domains and the effect of outside information on the system itself). Second, at least some subset of the knowledge comprising a C-module is innately given (hence universal). With regard to language, a strong case has been made for a universal grammar (UG), an innate system of mental representations, which is shaped by environmental input into a specific linguistic system (Chomsky, 1984; Chomsky, 1986). By analogy with UG, we can envision that each of the other possible C-modules mentioned above develops from an innate knowledge base: UPh, UBio, and so on.

Computational or performance modules ('P-modules' hereafter) are mechanisms that process and transform mental representations. They are only able to carry out computations on a restricted range of inputs, namely, those concerning a particular domain, and in processing these inputs they can only use their own proprietary principles and procedures (their own database, which may comprise a C-module). For instance, an arithmetic computational module will only provide solutions to arithmetic problems and will only use arithmetic operations to solve those problems. Fodor's landmark 1983 book on modularity focused on P-modules (while acknowledging the existence of C-modules), arguing in particular that language processing is a P-modular system.

In addition to the central properties of domain specificity and informational encapsulation, Fodor

suggested a number of other criterial properties of P-modules. Like reflexes, they function mandatorily when presented with an appropriate input, and they are very fast in their operation; consequently, their output is relatively shallow. There are three criteria that reflect their innate basis, distinguishing them from learned habits (which may also be fast and automatic): neural localization, a relatively fixed ontogenetic pace and sequence, and characteristic patterns of independent breakdown. Fodor (1983) provides evidence that language parsing (or perception) has all eight of these properties, though others dispute this (Marslen-Wilson and Tyler, 1987).

The big question about the architecture of the human mind concerns the extent to which it is modular as opposed to employing domain-general principles and processes. Fodor's (1983, 1989, 2000) answer is that only input and output systems (roughly, the various perceptual systems, motor systems, and language) are modular. The central cognitive systems, responsible for belief fixing and reflective thought, are content general and highly sensitive to contexts and individual utilities. So, according to Fodor, they are nonmodular (global, isotropic) and, as a result, are beyond the reach of scientific investigation.

The strict Fodorian view of a module, with its application only to peripheral mental systems, is widely seen as too restrictive (Karmiloff-Smith, 1992; Sperber, 1996, 2005; Carruthers, 2003, 2004). From an evolutionary perspective on human cognition (Cosmides and Tooby, 1994; Sperber, 1996), what characterizes a mental module is that it is a special-purpose mechanism attuned to regularities in a particular domain, a biological adaptation selected for its efficiency in dealing with problems specific to that domain. It will tend to employ principles and heuristics that have evolved for the task at hand and are not applicable to problems outside its domain.

On this broader view of a mental module, human cognitive architecture is likely to be massively modular. Not only perception but also many central conceptual systems are modular (Sperber, 1996, 2002; Carruthers, 2003). One central inferential capacity that has received much attention as a likely modular system is 'mind reading,' that is, the capacity to attribute mental states such as intentions and beliefs to others on the basis of observed behavior (Scholl and Leslie, 1999; Wilson, 2003). It is further claimed that the pragmatic capacity (that is, the ability to infer the intended meaning of communicative acts, whether verbal or nonverbal) is a sub-module of the mind-reading module, with its own special-purpose principles and mechanisms (Sperber and Wilson, 2002; Wilson, 2003).

Strong supporting evidence for any modularity claim comes from 'double dissociations,' where for one group of people a specific capacity (say, mind reading) is impaired while another (say, language) remains intact, and, for another group, the pattern is the reverse (see Shallice, 1988; Smith and Tsimpli, 1996; Wilson, 2003).

Monotonicity and Generalized Quantifiers

R Cann, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Many quantified noun phrases give rise to entailment relations between sentences that differ with respect to some modification of a verb phrase in their scopes. Consider the following sentences:

- (1a) No students laughed.
- (1b) No students laughed loudly.
- (2a) Every philosopher smokes.
- (2b) Every philosopher smokes heavily.

Whereas Example (1a) entails Example (1b), this is not the case with Examples (2a) and (2b). On the other hand, Example (2b) *does* entail Example (2a), whereas Example (1b) does not entail Example (1a). The important property to note here is that in the (b) sentences, the verb phrases pick out a smaller set of entities than the (a) sentences do (those who laugh loudly constitute a subset of those who laugh, and the set of heavy smokers is a subset of the set of smokers). So, the truth value of a sentence with *No students* in its subject position is unaffected if the denotation of its verb phrase (VP) is reduced. At the same time, the truth value of a sentence with *every philosopher* as subject remains unaffected whenever the denotations of its VP is extended. These entailment relations are known as 'monotonicity' relations, and *no students* is said to be 'monotone decreasing' (MON↓); *every philosopher* is 'monotone increasing' (MON↑). So a quantified noun phrase (QNP) is monotone just in case:

$$\text{QNP VP}_1 \vdash \text{QNP VP}_2,$$

where \vdash is the entailment relation and the denotation of VP_1 contains that of VP_2 (decreasing) or vice versa

(increasing). Some further examples of monotone-increasing quantifiers are shown in the following examples:

- (3a) Proper names:
Kim sang loudly \vdash Kim sang.
- (3b) *Many N*:
Many lecturers eat a lot of chocolate \vdash
Many lecturers eat chocolate.
- (3c) *At least n N*:
At least three cats were killed by the dog \vdash
At least three cats were killed.
- (3d) *Most N*:
Most students passed with high marks \vdash
Most students passed.
- (3e) *More than half of the N*:
More than half of the congregation came to church on time \vdash
More than half of the congregation came to church.

There are fewer monotone-decreasing quantifiers that do not directly involve a negation particle:

- (4a) *Few N*:
Few lecturers eat chocolate \vdash
Few lecturers eat a lot of chocolate.
- (4b) *At most n N*:
At most three cats were killed \vdash
At most three cats were killed by the dog.
- (4c) *Less than half of the N*:
Less than half of the congregation came to church \vdash
Less than half of the congregation came to church on time.

Not all quantifiers are monotonic, however (represented as MON~):

- (5a) *Exactly n N*:
Exactly three cats were killed \nvdash
Exactly three cats were killed by the dog.

(5b) *A few N*:

A few lecturers eat chocolate ~~not~~

A few lecturers eat a lot of chocolate.

Interestingly enough, it seems to be universally the case that ‘simple’ noun phrases – i.e., proper names, noun phrases consisting of a simple determiner plus noun, and quantifier noun phrases such as *everyone*, *no one* – are always monotonic. Only noun phrases containing complex determiners, such as *a few*, *exactly five*, *all but seven*, etc., may not be.

To give more precise definitions and to explore the properties of monotonicity, most semanticists follow Montague (1973) in taking QNPs as denoting **generalized quantifiers**. These are defined as higher order denotations, picking out sets of sets of entities, each set bearing some specified relation to the set of entities denoted by the common noun (phrase) in the QNP. Thus, *every philosopher* denotes the set of all sets that contain as a subset the set of philosophers. *Every philosopher smokes* expresses a true proposition, therefore, just in case the set of smokers is a superset of the set of philosophers, in which case $\| \text{smoke}' \| \in \| \text{every philosopher} \|$ (where $\| \alpha \|$ represents the denotation of α). More generally, given a sentence consisting of a quantified noun phrase in subject position and some verb phrase, $\| \text{QNP VP} \|$ is then defined as being true just in case $\| \text{VP} \| \in \| \text{QNP} \|$.

The monotonicity properties of generalized quantifiers have been the object of considerable research within semantics since the seminal work of Barwise and Cooper (1981). Within this framework, the monotonicity property of a quantifier is easily defined. A generalized quantifier QNP VP is as follows:

(6a) MONOTONE INCREASING just in case whenever $\| \text{VP}_1 \| \in \| \text{QNP} \|$ then $\| \text{VP}_2 \| \in \| \text{QNP} \|$ where $\| \text{VP}'_1 \| \subseteq \| \text{VP}'_2 \|$.

(6b) MONOTONE DECREASING just in case whenever $\| \text{VP}'_1 \| \in \| \text{QNP} \|$ then $\| \text{VP}_2 \| \in \| \text{QNP} \|$ where $\| \text{VP}_2 \| \subseteq \| \text{VP}'_1 \|$.

Quantified noun phrases may combine with the ‘Boolean’ connectives *not*, *and*, *or*, and these combinations may have an effect on the monotonicity of the resulting quantifier. For example, negation reverses the direction of the monotonicity of a quantifier, whether it is internal (corresponding to VP negation) or external (corresponding to the negation of the QNP).

(7a) Not all philosophers smoke \vdash Not all philosophers smoke heavily.

(7b) All students don’t like semantics \vdash All students don’t like formal semantics.

(7c) Few lecturers don’t eat a lot of chocolate \vdash Few lecturers don’t eat chocolate.

Formally, negation of quantifiers can be defined as follows:

External negation :

$$\| \neg \text{QNP} \| = \{ X \subseteq E \mid X \notin \| \text{QNP} \| \}. \quad (8a)$$

Internal negation :

$$\| \text{QNP} \neg \| = \{ X \subseteq E \mid (E - X) \in \| \text{QNP} \| \}. \quad (8b)$$

To see the effects of these definitions, consider the negation of the quantifier *all N*:

$$(9a) \| \text{all N} \| = \{ X \subseteq E \mid \| \text{N} \| \subseteq X \} = \{ X \subseteq E \mid \| \text{N} \| \cap X = \| \text{N} \| \}.$$

$$(9b) \| \neg \text{all N} \| = \{ X \subseteq E \mid X \notin \| \text{all N} \| \} = \{ X \subseteq E \mid \| \text{N} \| \cap X \neq \| \text{N} \| \} \\ \text{(external negation plus (9a))}.$$

$$(9c) \| \text{all N} \neg \| = \{ X \subseteq E \mid (E - X) \in \| \text{all N} \| \} \\ = \{ X \subseteq E \mid \| \text{N} \| \cap (E - X) = \| \text{N} \| \} \\ = \{ X \subseteq E \mid \| \text{N} \| \cap X = \emptyset \} \\ = \| \text{no N} \| \\ \text{(internal negation plus (9a))}.$$

To see that negation does indeed reverse monotonicity, consider how the definitions in Examples (8a) and (8b) affect a monotone increasing quantifier. Assume a QNP is $\text{MON}\uparrow$ and that X and Y are arbitrary sets such that $X \subseteq Y$, so that ‘QNP X ’ entails ‘QNP Y ’ (where X and Y are VPs that denote X and Y , respectively). If $Y \in \| \text{QNP} \neg \|$, then $(E - Y) \in \| \text{QNP} \|$ (by Example (8b)) and $(E - Y) \subseteq (E - X)$, so $(E - X) \in \| \text{QNP} \|$ and hence $X \in \| \text{QNP} \neg \|$. So ‘QNP not Y ’ entails ‘QNP not X ,’ as required. Analogously, if $Y \in \| \neg \text{QNP} \|$, then $Y \notin \| \text{QNP} \|$, so that $X \notin \| \text{QNP} \|$ and hence $X \in \| \neg \text{QNP} \|$. So ‘not QNP Y ’ entails ‘not QNP X ,’ and both forms of negation thus make a monotone-increasing quantifier into a decreasing one.

Note that because $\text{QNP} = \neg \neg \text{QNP} = \text{QNP} \neg \neg$, any decreasing simple quantifier is a negated form of a simple increasing one. This may explain why negating decreasing QNPs is generally ill formed, because the corresponding simple increasing QNPs could be used.

(10) *Not few students = Many students.

Monotonicity is maintained if two (or more) QNPs with the same direction of monotonicity are conjoined by *and* or *or*.

(11a) A student and every lecturer were snoring loudly \vdash

A student and every lecturer were asleep.

(11b) Bill or both women ran home quickly \vdash Bill or both women ran home.

(12a) No student and not all lecturers were asleep \vdash No student and not all lecturers were snoring loudly.

- (12b) At most ten men or less than half the women
ran home \vdash
At most ten men or less than half the women
ran home quickly.

Again it is fairly easy to show that this must be the case using the formal apparatus of generalized quantifiers, given conjunction interpreted as involving set intersection and disjunction as set union, as in Examples (13a) and (13b):

- (13a) $\parallel NP_1 \parallel$ and $NP_2 \parallel = \parallel NP_1 \parallel \cap \parallel NP_2 \parallel$.
(13b) $\parallel NP_1 \parallel$ or $NP_2 \parallel = \parallel NP_1 \parallel \cup \parallel NP_2 \parallel$.

We take the persistence of monotonicity properties with *and* as an illustration of how the proofs of these four theorems are established:

Assume that QNP_1 and QNP_2 are both $MON\uparrow$ and that X and Y are arbitrary sets such that $X \subseteq Y$. If $X \in \parallel QNP_1 \parallel \cap \parallel QNP_2 \parallel$, then it must be the case that $X \in \parallel QNP_1 \parallel$ and $X \in \parallel QNP_2 \parallel$. So, by increasing monotonicity, $Y \in \parallel QNP_1 \parallel$ and $Y \in \parallel QNP_2 \parallel$. Hence, $Y \in \parallel QNP_1 \parallel \cap \parallel QNP_2 \parallel$. QED.

Barwise and Cooper (1981) suggest that coordination of noun phrases is constrained by monotonicity:

Co-ordination constraint: Two NPs can be coordinated by conjunction (*and*) and disjunction (*or*) iff they are both monotone increasing or both monotone decreasing.

- (14a) No student and every lecturer liked the book.
(14b) Most students and every lecturer liked the book.
(14c) *No student and most lecturers liked the book.
(14d) *No student and a lecturer liked the book.

On the other hand, the connective *but* seems to require quantifiers with different monotonicity:

- (15a) Every woman but no man agreed with the Prime Minister.
(15b) No student but most lecturers liked the book.
(15c) *Most students but every lecturer liked the book.

However, there are many counterexamples to these apparent constraints, so they cannot be adopted universally and some other explanation remains to be given for the ill-formed examples.

- (16a) At least three cats and at most four dogs (were killed on this road last year).
 $MON\uparrow$ and $MON\downarrow$
(16b) Bill and a few women (met in the pub).
 $MON\uparrow$ and $MON\sim$:

Although the constraint against conjoining quantified noun phrases with different monotonicity properties cannot be maintained as a linguistic universal, there is one property that is fully robust. Negative polarity items such as *any* or *ever* are typically within the scope of negation (Examples (17a)–(17d) (Klima,

1964), but they also appear in the scope of certain types of quantified noun phrases that do not contain an overt negation marker (Examples (18a)–(18d)). The latter are all monotone-decreasing quantifiers and the generalization in Example (19) appears to be universally true (Ladusaw, 1983):

- (17a) John didn't eat any chocolate.
(17b) *John ate any chocolate.
(17c) No students were ever early.
(17d) *All students are ever early.
(18a) At most five residents saw anything.
(18b) Few students fail any exams.
(18c) *Many students fail any exams.
(18d) Less than half of the congregation ever stays to the end of the service.
(18e) *Exactly five people ever sing loudly enough.

(19) Negative polarity items may appear in the scope of monotone-decreasing quantifiers but not in the scope of nonmonotonic or monotone-increasing quantifiers.

In the discussion so far, the monotonicity of quantifiers have been treated as referring to entailment relations involving increases or decreases in their **scope**, as denoted by a VP with which they may combine. Because quantified noun phrases consist of a determiner plus a common noun phrase, the latter, like verb phrases, are taken in extensional semantic theories to denote sets; the theory of generalized quantifiers conceptualizes **determiners** as denoting relations between sets:

- (20) $DET(A) (B)$, where A is the set denoted by the common noun phrase (the restrictor) and B is the set denoted by the verb phrase (the scope).

Given this view, it is natural to consider whether monotonicity applies not only to variations in the scope of a determiner but also in its restrictor. Clearly, this is the case, and restrictor (or left) monotonicity can be defined in the same way as scope (or right) monotonicity was defined for QNPs (some examples are given in Example (24)).

- (21) A determiner DET is LEFT (OF RESTRICTOR) MONOTONE INCREASING ($\uparrow MON$) iff
 $DET N_1 VP \vdash DET N_2 VP$, where
 $\parallel N_1 \parallel \subseteq \parallel N_2 \parallel$.
A student with red hair is singing entails
A student is singing.
(22) A quantifier DET is LEFT (OF RESTRICTOR) MONOTONE DECREASING ($\downarrow MON$) iff
 $DET N_1 VP \vdash DET N_2 VP$, where
 $\parallel N_2 \parallel \subseteq \parallel N_1 \parallel$.
No student failed their degree exams entails
No student of linguistics failed their degree exams.
(23) A quantifier DET is LEFT (OF RESTRICTOR) NONMONOTONIC ($\sim MON$) iff

DET N_1 VP $\not\models$ DET N_2 VP, where
 $\|N_2\| \subseteq \|N_1\|$ or $\|N_1\| \subseteq \|N_2\|$.

Exactly five students failed badly neither entails
 nor is entailed by *Exactly five students of
 linguistics failed badly*.

- (24) \uparrow MON \uparrow A, some, at least n
 \downarrow MON \downarrow No, less than n
 \downarrow MON \uparrow Every, all
 \downarrow MON \uparrow Not all, not every
 \sim MON \uparrow Most, many
 \uparrow MON \sim Some but not all
 \sim MON \downarrow Few
 \sim MON \sim Exactly n

Montague Semantics

T M V Janssen, ILLC, University of Amsterdam, Amsterdam, The Netherlands

Historical Background

Montague semantics emerged around 1970, and constituted a fundamentally new approach to the semantics of natural language. In order to understand the importance of this approach, it is useful to consider the situation in that period of some neighboring disciplines of semantics: philosophy of language, philosophical logic, and linguistics. These subjects are considered below, a more extended picture of the historical background is given by Partee and Hendriks (1997).

One of the subjects studied in philosophy of language was meanings of natural language, and these were (before 1970) sometimes represented in some or other logic. The mapping between a sentence and its logical representation was made in an *ad hoc* way; it was more or less stipulated which formula was the correct meaning representation of a given sentence. The situation could be characterized as follows: a 'bilingual logician,' who knew logic and who knew a natural language, provided the formula. It was noticed that there could be a large difference between

the sentence and the formula, and a dominant view of these matters at that time was the so-called 'misleading form thesis,' saying that there is a sharp distinction between the grammatical and the logical form of sentences, and that the grammatical form disguises the logical form to such an extent that they cannot be related in a systematic way. It was sometimes even proposed to design for certain purposes an improved version of natural language in which the form does not obscure the meaning.

In philosophical logic there is a tradition to study words of natural language that are philosophically interesting. Examples are 'necessarily' and 'possibly.' Axiom systems for these notions were designed which expressed their properties. A jungle of systems of modal logics arose, motivated by different properties of embeddings of these notions. Kripke brought about, in the mid-1960s, an enormous change in this field. He introduced semantic models for modal logics, thereby making it possible to conceive modal logic in the same way as mathematical logic: as a formal language with a model-theoretic semantics. The variety of systems could be structured by conceiving them as expressing relations between possible worlds in a model.

Around 1960, Chomsky brought about great changes in linguistics by introducing mathematical standards of explicitness. He developed the tools for this (context-free grammars and transformations),

and syntax became a flourishing branch of linguistics. There was some attention to semantic issues, such as whether transformations were meaning-preserving, or what would be the input for a semantic component, but the theory was a theory about syntax that did not deal explicitly with semantics.

These three lines were brought together by Richard Montague. He was a mathematical logician who had made important contributions to the foundations of set theory. He was attracted by Chomsky's formal treatment of natural language, but unsatisfied by its (lack of) treatment of semantics. Therefore he developed an alternative to the Chomskyan approach that satisfied his (logical) standards. He presented a fragment of English and provided it with a rigorous model-theoretic interpretation. Most important is the fact that the relation between a sentence and its meaning is defined in a systematic way. It became possible, for the first time in history, to calculate which meaning is associated with any given sentence, hence to make predictions concerning semantics.

By developing his grammar model, Montague provided evidence for his opinion that there is no important theoretical difference between natural languages and the languages studied by logicians: both can be dealt with using the same methods and with the same mathematical rigor (Montague, 1970a: 189; Montague, 1970b: 313; Thomason, 1974: 188, 222). The title of one of Montague's first publications on this subject provides clear evidence of his position: 'English as a formal language' (Montague, 1970a).

Aims

The aim of Montague semantics is to describe, predict, and explain semantic relations between natural language utterances, an aim it shares with other theories. In the present section, some important semantic relations between natural language utterances will be introduced by means of examples, viz. entailment, valid reasoning, synonymy, and ambiguity. The examples given here are realistic in the sense that they are treated within the field of Montague semantics, thus giving an impression of the variety of phenomena that are studied. The examples that occur without reference are within the fragment of Montague (1973), or are variants of such examples.

An important semantic relation is the 'entailment' relation between sentences, say A and B. This means that whenever A is accepted as being true, B must also be accepted as being true, on grounds of meaning properties. Sentence (1) entails sentence (2):

- (1) Mary is singing and dancing.
- (2) Mary is singing.

This entailment, however, does not hold for all grammatical subjects: witness (3) and (4), where in fact the inverse relationship holds.

- (3) No-one is singing and dancing.
- (4) No-one is singing.

This means that the noun phrases have to be divided into two classes, one for which the entailment holds, and one for which it does not. Then one would like to have an explanation of why precisely *two girls* and *both girls* are in different classes (*Both/precisely two girls were singing and dancing*), and a prediction concerning compound terms like *few girls and many boys*. For an overview of properties of quantified noun phrases, see Keenan and Westerstahl (1997) and the article **Quantifiers: Semantics**.

An example of a different nature is the following. (5) entails (6) (see Dowty, 1979):

- (5) John cools the soup.
- (6) The soup cools.

Here, one would like to have a description of the relation between the meaning of *cool* as a transitive causative verb and *cool* as an intransitive verb. And one would like to know why the implication holds for *boil* but not for *stir*.

A 'valid reasoning' is a generalization of entailment that involves more sentences than two. If someone accepts (7) and (8), they may conclude correctly (9):

- (7) John sings.
- (8) John is a man.
- (9) A man sings.

A more intricate example is (Groenendijk and Stokhof, 1982):

- (10) John knows whether Mary comes.
- (11) Mary comes.
- (12) John knows that Mary comes.

Here, one sees that there is a relation between the meaning of the *whether* clause and the *that* clause. It seems that the latter is weaker. However, the relation is more complicated: if one has the negated version (11a), then (12a) follows from (10) and (11a)

- (10) John knows whether Mary comes.
- (11a) Mary does not come.
- (12a) John knows that Mary does not come.

Hence the relation between the *whether* clause and the *that* clause depends on the factual situation.

A special case of entailment is 'synonymy.' Sentences are called synonymous just in case they entail

each other. For example, sentences (13) and (14) are synonymous:

(13) John or Mary comes.

(14) John comes or Mary comes.

Another example of synonymy is (Partee and Bach, 1981):

(15) Mary admires herself, and Sue does too.

(16) Mary admires herself, and Sue admires herself.

It may seem that the meaning of the *does too* clause can be found by the substitution of a phrase that occurs elsewhere in the sentence. This is, however, not always the case. It is, for instance, possible to conclude from (17) to (18).

(17) Mary believes that she is ill, and Sue does too.

(18) Mary believes that she is ill, and Sue believes that Mary is ill.

This illustrates the important phenomenon of ‘ambiguity.’ Sometimes a sentence can be understood in two or more ways corresponding with distinct consequences. From (17), one may conclude either that

(19) Sue believes that Mary is ill.

or that

(20) Sue believes that she (= Sue) is ill.

Another example of ambiguity is (e.g., Janssen, 1983, 1986b):

(21) Ten years ago, John met the president of the USA.

(22) The president of the USA is Bush.

On the one reading of (21), one may conclude that ten years ago John met Mr. Bush. On the other reading, this does not follow since John met the person who was president ten years ago. This ambiguity clearly concerns the functioning of tense operators.

The decision whether a sentence is ambiguous or vague is not always clear. Consider (23):

(23) Two girls are five sandwiches.

One may ask what counts as a source of semantic ambiguity; if it makes a difference whether they shared all five sandwiches; whether the sandwiches were distributed between the girls; or if it makes a difference whether they ate together or whether each girl ate on her own. Maybe the issue would be more exciting if the sentence was *Two girls shot five men* and one had to judge the girls. Verkuyl and Van der Does (1996) argue that (23) has one meaning, whereas they refer to other authors who argue for a fourfold or even ninefold ambiguity.

So far, only examples of relations between declarative sentences have been cited. Other types of sentences take part in ‘other semantic relations,’ as between the questions (24) and (25):

(24) Which girls came to the party?

(25) Did Mary come to the party?

In this example, there is nothing like the acceptance of a premise or of a conclusion. Nevertheless, there is a relation: every answer to the first implies an answer to the second question. The meanings assigned to these questions should account for this (Groenendijk and Stokhof, 1989).

Sequences of sentences likewise have logical properties. Consider (26) and (27).

(26) A man walks in the park. He whistles.

(27) A man in the park whistles.

This example puts a requirement on the treatment of texts. The meaning of the two sentences together should be equivalent to the meaning of the single sentence.

All examples discussed in this section have the common feature that they do not depend on specific details of the meanings of the words involved (except for logically crucial words such as *not* or *and*). It is, for example, possible to account for the inference from (1) *Mary is singing and dancing* to (2) *Mary is dancing* without describing the differences between *dancing*, *jogging*, and *walking*. Each of the examples can be replaced by another which exhibits the same pattern but uses other words. The examples illustrate that in Montague semantics one is mainly interested in structural aspects of the semantic relations between sentences, that is, in the systematic aspects of meaning. The formalization of what meanings are, does not need to go further than is required for an adequate account of these structural aspects.

The Compositional Approach

The most salient aspect of Montague semantics is the systematic way in which natural language expressions are connected with their respective meanings. This relation is characterized by the principle of compositionality of meaning. Such a principle can, in several formulations, be found in many disciplines that deal with semantics, such as linguistics, philosophy, and computer science. In philosophy of language, it has a long tradition and is often called ‘Frege’s principle.’ The version of this principle that describes the method of Montague grammar most explicitly is (Partee *et al.*, 1990: 318):

The meaning of a compound expression is a function of the meanings of its parts and of the syntactic rules by which they are combined.

The formulation of the principle contains several vague terms, and a proper application of the principle requires a more formal interpretation (for a discussion of the principle, its formalization, consequences, and its status, see **Compositionality, Aspects of**). The main points of its formalization are summarized here.

The syntax of the grammar consists of rules which express how new expressions can be formed from already available ones. The rules are, therefore, operations which act on inputs and yield an output. If an expression *E* is the output of the application of a rule *R*, then the inputs that form *E* are defined as being the parts of *E* in that derivation. The semantic component is organized in a parallel way: there are semantic rules that operate on input meanings and yield an output meaning. The crucial factor for obeying compositionality is that there is a strict correspondence between syntax and semantics. For each syntactic rule, there should be a corresponding semantic rule expressing the semantic effect of that syntactic rule. Compositionality is taken to be not an empirically verifiable property of natural language but a methodological principle: it constrains the organization of the grammar.

Consider example (28):

(28) Penguins do not fly.

A very simple grammar will be considered, naively as regards its meaning. For example, it will be assumed that the sentence says something about all penguins, whereas plurals without article usually have a more subtle meaning. The intention of this example is, however, only to illustrate the *method* of compositionality.

Suppose the grammar has as basic expressions the plural noun phrase *penguins* and the verb *fly*. A rule (say *R1*) forms the verb phrase *do not fly* from this verb. Furthermore, there is a rule (*R2*) combining a noun phrase with a verb phrase to form a sentence, by concatenating them and performing the required changes in the verb phrase for agreement and similar trimmings. Then sentence (28) has, according to this grammar, two parts: *penguins* and *do not fly*, and the latter phrase has in turn one part: *fly*.

This derivation might be represented in the form of a tree, as in **Figure 1**. Note that this tree does not

Figure 1 The derivation tree of 'Penguins do not fly.'

depict the constituent structure of the sentence; for example, there are no separate nodes for *do* and *not*. The tree shows how the sentence is formed; it is a construction tree or derivation tree. There is no *a priori* reason why the derivation would be identical to the constituent structure of the result (one might impose this as an additional requirement).

Of course, there might be good arguments for preferring a different grammar. Thus, one might construct (28) out of the positive sentence *Penguins fly*, or, alternatively, from *penguins*, *fly*, and *not*. In the former case the rule has one part, and in the latter case three parts. Compositionality as such provides no criterion for such issues. The best choice is probably to be discovered by considering more examples and larger fragments.

The principle of compositionality states that the meaning of the sentence is a function of the meanings of its parts, hence (according to the given grammar) of *penguins* and *do not fly*. Of course, the meaning of the latter is, in turn, a function of the meaning of its part *fly*. So, in the end, the meanings of the basic expressions are attained. Adopting for the moment a very simple conception of meaning that will be revised in the next section, one can take the meaning of *fly* to be the set of individuals who fly, and the meaning of *penguins* to be the set of individuals who are penguins.

According to the rules, the verb phrase *do not fly* has only *fly* as a part, and therefore the meaning of this verb phrase has to be formed out of the meaning of *fly*. So there has to be a semantic operation that expresses the meaning of negating a verb. For the moment, the meaning of *do not fly* is, in analogy of that of *fly*, the set of individuals who do not fly. The operation that forms this meaning from the meaning of *fly* is the formation of a set complement. In line with the above assumptions about meaning, one may say that the sentence means that the set of penguins is included in the set of nonflying individuals. This meaning is to be obtained from the meanings of its parts: from the set of penguins, and from the set of individuals who do not fly. This can indeed be done.

The situation is as follows. Two syntactic rules (*R1* and *R2*) are each accompanied by a semantic interpretation (*M1* and *M2*, respectively):

R1: negating a verb

M1: complement formation

R2: concatenating a noun phrase with a verb phrase, performing agreement changes

M2: set inclusion

In this section, the method of compositionality has been exemplified. The crucial aspect is the correspondence between syntax and semantics. One might change the concept of meaning used above, or change

the syntax used; but as long as the correspondence remains intact, the grammar can be seen as an instance of Montague grammar. This characterization of Montague's method is given in a formal mathematical terminology in his paper 'Universal grammar' (Montague, 1970b).

Interpretation in a Model

In Montague grammar, as well as in all other formal theories of semantics, the natural language expressions are interpreted in a class of abstract models. For example, a name like *John* is associated with an individual in such models, and an adjective like *brave* is a property. Each model is constructed out of a number of basic sets by means of standard constructions, and the result can be restricted by 'meaning postulates.' The most characteristic feature of the models in Montague grammar is the distinction made between the 'extension' of an expression and its 'intension,' a distinction that will be the topic of the next section. In the present section, the status of the model and its connection with natural language will be considered.

The model in which humans interpret natural languages has, of course, a certain resemblance to the real world, but it should not be conceived of as a model of the real world. There are two differences. First, in language, one speaks not only about the real world, past, present, and future, but also about situations that might be the case. Even though unicorns do not exist, one can speak about them, and the sentences used have semantic properties that should be dealt with. The model thus embraces much more than reality.

Second, as far as the model is connected with reality, it is a model of how natural language 'conceives' of it. This conception might be different from the real situation. Examples are mass nouns like *water* or *air*. In natural language, they are used in a different way from count nouns such as *chair* or *flower*. The mass noun *water* is used as if every part of a quantity of water is again water; as if it had no minimal parts. The same holds for *air*. Although in reality water has minimal molecules, and air is a mixture, the model will not reflect that fact (Pelletier and Schubert, 2003).

Although the model does not reflect reality, one can be interested in the relation which it has with reality. Examples are the relation between *blue* and the frequencies of light, or the number of exceptions accepted when it is said that *all ravens are black*. This kind of research is rare in Montague grammar, however, because it amounts to the analysis of specific words, whereas in Montague grammar one is mainly interested in the more structural aspects of the semantics of natural language.

The model, not being a model of reality, might be regarded as a model of how the human mind conceives reality. Although psychological reality is not one of the claims of Montague grammar (it is so in some other theories), the issue has received some attention (e.g., Dowty, 1979: ch. 8).

The connection between natural language and the model can be made in two ways. One method, the direct one, was followed in the section 'The Compositional Approach': for a word, some element (set, function) in the model is given as the meaning of that word, and for each syntactic rule a corresponding meaning operation is given. This method is used in Montague's first publication (Montague, 1970a), and in a few other publications as well (e.g., Keenan and Faltz, 1985). The other method is the indirect one: natural language is translated into some logical language, which is interpreted in a model. If this translation is compositional, and the interpretation of the logical language is compositional, then the combination of the two processes is a compositional process of meaning assignment. Care has to be taken that the logic is used as an auxiliary language only, so that this intermediate language can in principle be eliminated. This implies that every operation that is performed in the logic should have an interpretation in the model. This indirect method is the standard method in Montague grammar; usually, (variants of) intensional logic are used as the intermediate language.

Extension and Intension

An important decision concerns the question of how to model meaning. Previously, the meaning of *penguins* was defined as the set of penguins, and of *fly* as the set of flying individuals. Applying the same approach to *the president of the USA* [example (22)], would yield as meaning the individual Bush, and applied to *unicorn* (assuming there are none) the empty set. This approach would, however, give results that are intuitively incorrect. It would have the consequence that in case neither unicorns nor centaurs exist, the meaning of *unicorn* would be equal to the meaning of *centaur*. As for *the president of the USA*, it would have the undesirable consequence that its meaning changes after each election. Examples like these have led to the distinction between two kinds of interpretation: extension and intension.

At the time of writing, the president of the USA is Mr Bush, but at other moments in time a different person will be president, and in another course of events Mr Bush could have lost the election and Mr Kerry would be president. The model in which natural language is interpreted has components dealing with this. It has a collection of time points for

dealing with changes in the course of time, and it has a collection of so-called 'possible worlds.' These possible worlds represent the possibility that Kerry has won. They also represent the possibility that unicorns exist. Intensions are functions with possible worlds and time points as domain. The intension of *the president of the USA* is a function from time points and possible worlds that yields an individual (the president at that moment in that possible world), and the intension of *unicorn* is the function that yields for each possible world and time point a set of individuals (the unicorns). The extension of an expression is the value of the intension function with respect to a given world and time point, for example, the moment now in the actual world. Then the extension of *the president* is the president now (Mr Bush), and the corresponding extension of *unicorn* is the actual set of unicorns. The extension of a sentence is traditionally identified with its truth value. Thus, the extension of *John kisses Mary* is true just in case John kisses Mary. The intension is the function which says, for each possible world, in which moments John kisses Mary.

Since there are possible worlds in which there are unicorns but no centaurs, the words *unicorn* and *centaur* have different intensions. As a consequence, sentences (29) and (30) will have different intensions too.

(29) John seeks a unicorn.

(30) John seeks a centaur.

Thus, using intensions, the nonsynonymy of (29) and (30) can be accounted for. For this purpose, no further information concerning relations between different possible worlds is needed, nor any information concerning relations between time points. This holds for all examples mentioned in the section 'Aims,' and therefore the set of possible worlds and the set of time points are usually introduced as just sets without further specification. This is, however, not always sufficient.

If one is interested in tense phenomena in natural language, then more has to be said about the moments of time, for example that they are linearly ordered, and whether they are indivisible points or intervals with a duration. If one is interested in causatives (*John broke the glass*) or counterfactuals (*If Mary did not come, John would fly*), then the set of possible worlds needs more structure. For dealing with these phenomena, it is crucial to know how the world was just before the breaking of the glass, or which world resembles the present one except for the coming of Mary.

The above discussion shows that the formalization of the intuitive notion of meaning as intension is much better than as extension. However, intensions

only deal with those aspects of meaning that have to do with truth and denotation, and neglect aspects such as style, new information versus old information, etc. Therefore, they can only be regarded as a restricted approximation of meaning. Even accepting this limitation, however, intensions are still not completely satisfactory. At important shortcoming concerns tautologies. Consider (31):

(31) Bill comes or does not come.

The intension of this sentence is the function that always yields 'true.' Hence (32) and (33) have the same intension.

(32) John comes.

(33) John comes and Bill comes or does not come.

This causes problems with embedded clauses. Sentences (34) and (35) will have the same intension, whereas they should not be equivalent since Mary's beliefs in (34) do not concern Bill; she may not even know about his existence:

(34) Mary believes that John comes.

(35) Mary believes that John comes and that Bill comes or does not come.

The conclusion is that intensions are not fine-grained enough to distinguish the meanings of sentences like (34) and (35). Several improvements have been proposed, such as structured intensions (Lewis, 1970), and an approach based on partial functions (Muskens, 1989).

A Small Fragment

This section presents as examples three sentences and their treatment. The treatment given in Montague (1973) will be followed, except for one detail (see next section). In the course of the presentation, some important features of intensional logic will be explained.

The sentences are:

(36a) John walks.

(37a) A man walks.

(38a) Every man walks.

These sentences are very simple, and it is easy to present their interpretation in traditional predicate logic:

(36b) $walk(john)$

(37b) $\exists x[man(x) \wedge walk(x)]$

(38b) $\forall x[man(x) \rightarrow walk(x)]$

One immediately sees that these three sentences are syntactically much alike (a subject and a verb), but the formulas in predicate logic are rather different: two with a quantifier (different ones!), and in each case another main operator (\rightarrow , \wedge , and predicate application). What makes it interesting to present these examples here is not the meaning assigned to them, but the fact that these very different meanings can be derived compositionally from the corresponding sentences.

All three sentences are built from a singular noun phrase and the verb *walks*, and for this reason one can design a single syntactic rule that combines a noun phrase and a verb. Since in Montague grammar there is a correspondence between syntactic rules and semantic rules, one also has to design a rule that combines the meaning of the verb with the meaning of the noun phrase. This in turn requires that there be meanings for verbs and for noun phrases. These meanings will be discussed first, then the semantic rule will be designed.

As explained in the previous section, predicates are given intensions as meanings: functions from possible worlds and moments of time to sets of individuals. Thus, the intension, or meaning, of the verb *walk* is a function from possible worlds and moments of time to sets: for each possible world and each moment of time, there is a set (possibly empty) of individuals who walk. Such an intension is called a 'property.' For the noun phrases, it is more difficult to select a format that allows these meanings to be rendered uniformly. In order to keep the calculus going in a maximally uniform way, all noun phrase meanings should preferably be of the same type. This requirement is easily seen to be nontrivial, as, for example, the expression *every man* extends over sets of possibly many individuals, where *John* seems to refer to one individual only.

Montague proposed (1973) to model the meaning of a noun phrase as a set ('bundle') of properties. An individual is, in this approach, characterized by the set of all its properties. This is possible since no two individuals share all their properties at the same time, if only because the two cannot be at the same place at the same time. This approach permits generalization over all noun phrases referring to (sets of) individuals (see also Lewis, 1970).

Meanings of linguistic expressions (functions from world-time pairs to specific world extensions) are denoted by formulas in the language of intensional logic. The meaning of *John* will be denoted by:

$$(39) \lambda P[\forall P(\text{john})]$$

To explain this formula, the variable

$$(40) P$$

is a variable over properties of individuals: P may be replaced, for example, by the property 'walking.' The expression

$$(41) \forall P$$

denotes the extension of the property expressed by any predicate P in any given world at a given moment of time. Thus, for the actual world now.

$$(42) \forall P(\text{john})$$

is true if the predicate $\forall P$ holds for John now in this world, and false otherwise. Any property denoted by P can be abstracted by means of the lambda operator: λP . Lambda abstraction of (42) gives:

$$(43) \lambda P[\forall P(\text{john})]$$

which is the same as (39) above. This expression denotes a function which says, for any property α , given a world-time pair $\langle w, t \rangle$, whether John belongs to the extension of that property in $\langle w, t \rangle$. Let this function be called X_j . Some properties of this function will now be investigated.

According to the definition of X_j :

$$\begin{aligned} X_j(\alpha) \text{ is true if and only if } \alpha \text{ now holds for} \\ \text{the individual John, i.e., } \forall \alpha(\text{john}) \text{ is true,} \\ \text{and false otherwise} \end{aligned} \quad (I)$$

X_j is, therefore, the characteristic function of the set of properties that can be predicated of John. As usual in logic, this characteristic function can be identified with the set of properties that John has. X_j can therefore be seen as a formalization of the idea that the meaning of *John* is a set of properties.

This function X_j can be evaluated with as argument the property of being a man, that is, the function that yields for each index (i.e., for each world and time) the extension of the predicate *man*. The notation for this argument is:

$$(44) \wedge \text{man}$$

The symbol \wedge translates the predicate *man* into the language of intensional logic, where $\wedge \text{man}$ denotes the intension associated with *man*. X_j is now applied to this argument to obtain, using result (I).

$$\begin{aligned} X_j(\wedge \text{man}) \text{ is true if and only if } \wedge \text{man} \text{ now} \\ \text{holds for the individual John, i.e., if and only} \\ \text{if } \forall \wedge \text{man}(\text{john}) \text{ is true, and false otherwise} \end{aligned} \quad (II)$$

In the expression $X_j(\wedge \text{man})$, X_j can be replaced by its original definition (viz. (43)). Then, (45) is obtained.

$$(45) \lambda P[\forall P(\text{john})](\wedge \text{man})$$

Result (II) now states that this is equivalent with

$$(46) \quad \forall^{\wedge} \text{man}(\text{john}).$$

Thus, it has been shown, using semantic considerations, that it is allowed to substitute the argument $\wedge \text{man}$ for the variable P , an operation known as ‘lambda conversion.’ According to the definitions given with (41) and (44), $\forall^{\wedge} \text{man}$ denotes the present value of the property of being a man. Hence (46) and (45) are equivalent with (47)

$$(47) \quad \text{man}(\text{john})$$

Summarizing, the variable P in (45) has been replaced with the property $\wedge \text{man}$, which is in the range of P , and $\forall^{\wedge} \text{man}$ has been reduced to just man . As the operations concerned are admissible independently of the particular choice of the predicate man , the procedure can be generalized to all predicates of the same class (type).

To revert to the treatment of the simple sentence *John walks*, the syntax has, as stipulated earlier, a rule that combines a noun phrase with a verb to form a sentence. What is still needed is a semantic operation that matches the syntactic rule with its semantic consequences. The operation that does this is so-called ‘function application’: one of the two syntactic constituents acts as a function, while the other acts as argument (input). In this case, the verb meaning is allowed to act as the argument, and the noun phrase meaning as the function. The result of function application, in this case, is a function from world–time pairs to truth-values, or the set of world–time pairs where John walks.

According to the rule just given, the meaning of *John walks* is found by application of the meaning of *John*, that is (43), to the meaning of *walk*. This is denoted by:

$$(48) \quad \lambda P[\forall P(\text{john})](\wedge \text{walk})$$

This, as seen above, can be reduced, in two steps, to:

$$(49) \quad \text{walk}(\text{john})$$

which now gives the meaning representation aimed at.

For the other sentences, one proceeds analogously. The noun phrase *a man* is likewise translated as a set of properties:

$$(50) \quad \lambda P[\exists x[\text{man}(x) \wedge \forall P(x)]]$$

This denotes the characteristic function of the set of properties such that for each property in the set there is a man that has that property. The sentence *A man walks* is then represented as:

$$(51) \quad \lambda P[\exists x[\text{man}(x) \wedge \forall P(x)]](\wedge \text{walk})$$

which reduces to:

$$(52) \quad \exists x[\text{man}(x) \wedge \text{walk}(x)]$$

Analogously, every man walks is represented as.

$$(53) \quad \lambda P[\forall x[\text{man}(x) \rightarrow \forall P(\text{john})]](\wedge \text{walk})$$

or equivalently

$$(54) \quad \forall x[\text{man}(x) \rightarrow \text{walk}(x)]$$

This treatment illustrates some of the power of lambda abstraction and lambda conversion. The meaning of the verb is ‘plugged into’ the meaning of the noun phrase in the right position. Lambda calculus is frequently used in Montague grammar. Without the lambda operator, it would be impossible to maintain compositionality. Impressed by the power of lambdas, Barbara Partee once said: ‘Lambdas really changed my life.’ What has been, in the end, obtained as meaning representations for the three sentences discussed is nothing more than the formulas usually associated with them in elementary logic courses. There, however, they are found on intuitive grounds, whereas in Montague grammar they are the result of a formal system which relates syntax and semantics in a systematic way.

Some PTQ Phenomena

Montague worked out his ideas in a number of papers, the most influential of which is ‘The proper treatment of quantification in ordinary English,’ henceforth PTQ (Montague, 1973). This article deals with some semantic phenomena, all connected with quantifiers. Three such phenomena will be discussed here: identity and scope ambiguities (both presented here because they have been the subject of a great deal of discussion since the publication of PTQ), and the ‘de dicto–de re’ ambiguity, central to Montague grammar, and the origin of its trade mark, the unicorn.

The first phenomenon concerns problems with identity. Consider:

$$(55) \quad \text{The price of one barrel is \$1.00.}$$

$$(56) \quad \text{The price of one barrel is rising.}$$

$$(57) \quad \$1.00 \text{ is rising.}$$

It is obvious that (57) must not be allowed to follow logically from (55) and (56), as \$1.00 will remain \$1.00 and will neither rise nor fall. The same phenomenon occurs with temperatures, names, telephone numbers, percentages, and in general with all nouns which may denote values. The PTQ treatment of such cases is as follows. Prices, numbers, etc. are treated as basic entities, just as persons and objects. The expression *the price of one barrel* is semantically

a function that assigns to each world–time index a particular price. Such a function is called an ‘individual concept.’ In (55) an assertion is made about the present value of this function, but in (56) an assertion is made about a property of the function. Thus, the expression *the price of one barrel* is considered ambiguous between a value reading and a function reading. The difference in readings blocks the false conclusion (57).

In spite of criticisms, mainly related to the treatment of such nouns as basic entities (e.g., Bennett, 1976), the notion of individual concepts also seems useful to account for cases like the following (Janssen, 1984).

- (58) The treasurer of the charity organization is the chairman of the hospital board.
- (59) The treasurer of the charity organization has resigned.
- (60) The chairman of the hospital board has resigned.

Here, substitution *salva veritate* of terms under an identity statement seems to be running into difficulty. Again, one can say that (58) is a statement about the identity of the values of two different functions at a given world–time index, whereas (59) is a statement about the function (in Frege’s terms, about the *Wertverlauf*). Hence the nonvalidity of (60) as a conclusion is explained.

The second phenomenon is scope ambiguity. Consider

- (61) Every man loves a woman.

In PTQ, this sentence is considered to be ambiguous (though many linguists would disagree; see below). In the one reading, one particular woman is loved by all men, and in the other every man has at least one woman whom he loves. The first reading is given in (62), and is called the specific reading, or the wide scope reading for *a woman*. The second reading is given in (63); it is called the ‘narrow scope reading.’

- (62) $\exists x[\text{woman}(x) \wedge \forall y[\text{man}(y) \rightarrow \text{love}(y, x)]]$
- (63) $\forall y[\text{man}(y) \rightarrow [\exists x \text{ woman}(x) \wedge \text{love}(y, x)]]$

Many linguists consider (61) to be unambiguous. Well-known is the principle which states that the most plausible reading is given by the surface order of the quantified NPs (and of the negation). Following this principle, (61) has only one reading, viz. (63). Note that the reading expressed by (62) is a special case of (63). The principle has not remained unchallenged. Witness (64), where the most plausible reading is not given by the surface order.

- At the finish, a medal is available for all participants in the race.

There are other linguistic theories which also assign one reading to (61). But whether (61), the PTQ example, really is ambiguous is less relevant as long as there are sentences that do show scope ambiguities, which seems beyond doubt. For instance, previously an example involving tense was given (*Ten years ago, John met the president*). The machinery of PTQ for dealing with scope ambiguities is presented below.

Since the scope ambiguity does not seem to have a lexical source, the principle of compositionality of meaning requires the construction of two different derivations for the two readings. In PTQ, this is done as follows. First, the basic sentence (65) is formed, in which neither of the two noun phrases occurs but which contains indexed variables (he_n) instead:

- (65) $he_1 \text{ loves } he_2$.

Next, noun phrases are substituted for the variables. This can be done in two different orders. The noun phrase that is substituted last gets the widest reading. Thus, the specific reading (wide scope for *a woman*) is obtained from (65) by first forming (66).

- (66) Every man loves he_2 .

and then

- (67) Every man loves a woman.

These rules are called ‘quantification rules.’ The corresponding semantic rule leads to an interpretation equivalent to that of (62). For the other reading, the reverse order of quantifier substitution is used.

These quantification rules have met with some resistance from linguistic quarters, where they are looked upon as unusual creatures. Other solutions have been attempted, where the disambiguation is not done in the syntax. Cooper (1979) deals with scope phenomena in a separate component, a ‘storage’ mechanism. Hendriks (1993) uses rules which change the meaning of a noun phrase from a narrow scope reading to a wider scope reading.

The third phenomenon is the ambiguity of ‘de dicto’ versus ‘de re’ readings. To see the difference, first consider (68) and (69):

- (68) John finds a unicorn.
- (69) There is a unicorn that John finds.

Sentence (69) follows from (68). Yet (71) does not follow from (70):

- (70) John seeks a unicorn.
- (71) There is a unicorn that John seeks.

In fact, (70) is ambiguous between a specific reading in which there is a specific unicorn that John seeks,

and an intensional reading where John is said to engage in the activity of seeking a unicorn and nothing is implied about the real existence of such animals. The latter reading is usually called the ‘de dicto’ reading (‘de dicto’: Latin for ‘about what is said’). The former reading is the ‘de re’ reading (‘de re’: Latin for ‘about the thing’). The ambiguity is accounted for, in principle, in the following way. In the ‘de re’ reading, a relation is asserted to hold between two individuals. The ‘de dicto’ reading establishes a relation between John and the set of properties of a unicorn (i.e., the interpretation of the noun phrase *a unicorn*). Whether this way of analyzing and accounting for the ‘de dicto’ reading is satisfactory in all respects is a question still widely debated (see e.g., Gamut, 1991).

The two readings of *John seeks a unicorn* are obtained in the following way. For the ‘de re’ reading, a quantification rule introduces the expression *a unicorn*. And if the expression *a unicorn* is introduced directly, that is, without the intervention of a quantification rule, the result is the ‘de dicto’ reading. In principle, this method is analogous to the method used to express scope differences. One may, in fact, regard the distinction between ‘de dicto’ and ‘de re’ readings as a distinction due to scope differences of the intensional operator *seek*.

Developments

Montague (1973) (henceforth PTQ) signaled the start of a great amount of semantic research. Nowadays there are many linguistic theories that deal in a formal way with semantics, and certainly not all of them obey Montague’s compositional framework, but in one respect they are all indebted to him: lambdas are used frequently (see section ‘A Small Fragment’ for the power of lambdas). This section reviews some of the developments that have emanated since PTQ and remain more or less within his compositional framework.

In the first period one kept close to the style of PTQ: one widened the original fragment with new phenomena. A characteristic example is the title ‘A variation and extension of a Montague fragment of English’ (Bennett, 1976). In such articles one finds treatments of relative clauses, passives, scope, control, numbers, plurals, generics, complement structures, and deictic pronouns: most deal with English, some with other languages. For references to these early works see Partee (1976), Gamut (1991), and Dowty *et al.* (1981). Nowadays the habit of providing explicit fragments is abandoned: one focuses on some semantic phenomenon and provides rules for that phenomenon only.

The first broadening of the scope of Montague semantics was toward lexical semantics. In PTQ the words are regarded as basic and remain unanalyzed except for a few logically interesting words such as the verb *be*: often, however, it is linguistically interesting to carry the analysis of words further. Examples (5) and (6) featured the word *cool*, which can be an adjective, an intransitive verb phrase, and a causative verb, with related meanings. Such lexical analyses are given in Dowty (1979).

Montague used a primitive kind of syntax. On the one hand, this appears from the fact that the syntactic rules are not subject to any formal restriction; on the other hand, from the absence of grammatical features and a well-motivated constituent structure and grammatical functions. Soon after the publication of PTQ, proposals were made to incorporate syntactic know-how as developed in transformational grammar into Montague grammar (see, e.g., Partee, 1975 and Dowty, 1982). Partee’s ideas for combining Montague grammar with transformational grammar are worked out in the large grammar used in the machine translation project Rosetta (Rosetta, 1994).

Since the earliest years of Montague semantics there have been attempts to make the syntactic rules as restricted as possible by using only concatenation rules. As a consequence, the constituent structure of the natural language expression becomes isomorphic to its compositional analysis. Because of this feature, such approaches are said to obey ‘surface compositionality.’ The approach leads to (variants of) categorical grammar. An early advocate of this approach was Bach (see, e.g., Oehrle *et al.*, 1988); a recent monograph within the framework of Montague is Morill (1994). Surface compositionality requires a treatment of scope phenomena different than Montague’s. An important idea is the use of type shifting rules: such rules make the relation between a word and its semantic type less rigid than in PTQ, and therefore this approach is called ‘flexible Montague grammar.’ The method is useful for several phenomena (including scope); see Partee and Rooth (1983), Hendriks (1993), and Groenendijk and Stokhof (1989).

As explained previously, noun phrases are treated in PTQ as sets of properties. Consequently the determiner ‘every’ is a function from sets to sets: it can be conceived of as a relation between two sets (e.g., in ‘Every man dances’ as a relation between ‘man’ and ‘dance’). This abstract analysis of noun phrases opened the way to a new field: the theory of ‘generalized quantifiers,’ in which many phenomena concerning noun phrases are studied. The pioneering article is Barwise and Cooper (1981); monographs

are Keenan and Faltz (1985) and Winter (2001), (*see Quantifiers: Semantics*).

The largest linguistic units analyzed in PTQ are sentences. The task of extending Montague's method to discourses looked unrewarding at first, particularly in view of cross-sentential anaphora phenomena. The first step from sentence to discourse (Kamp, 1981) was, on certain details, not compositional. Later a compositional treatment was given (Groenendijk and Stokhof, 1991). The key feature of their approach was that the meaning of a sentence is not a truth value, but its information change potential: a function that changes the information state. This led to dynamic semantics, an approach in which several other 'information' phenomena can be analyzed (*see Dynamic Semantics*).

Also, the ontology used by Montague has been challenged. His ontology was based upon a hierarchy of typed sets, but several phenomena suggest a change. Mass nouns seem to ask for sets that do not have elements (Pelletier and Schubert, 2004). Nominalizations (as in *I love loving*) seem to ask for an alternative in which functions can have themselves as arguments; this leads to property theory (see, e.g., Chierchia, 1982). Perception verbs challenge the basic role of possible worlds. They are abandoned by Barwise and Perry (1983), who replace them by 'situations,' but a classical model with partial functions can also be used (Muskens, 1989). PTQ deals with only one type of language utterances, declarative sentences, and one may think that other utterances require other types. But questions can be treated without a new ontology, as is shown by the work on the semantics of questions and wh-complements (Groenendijk and Stokhof, 1982, 1989).

Further Reading

A well-known introduction to Montague grammar (especially written for linguists) is Dowty *et al.* (1981). An introduction with much attention paid to logical and philosophical motivation is Gamut (1991). An introductory article on 'Universal grammar' (Montague, 1970b) is Halvorsen and Ladusaw (1979), its mathematical background is investigated in Janssen (1986a) and discussed in Janssen (1997). Publications on Montague grammar often appear in *Linguistics and Philosophy*. Many references are given in Partee and Hendriks (1997), recent collections of papers about Montague grammar are Partee (2004), and Portner and Partee (2002).

Mood, Clause Types, and Illocutionary Force

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Sadock and Zwicky (1985) surveyed 35 languages representing a wide range of language families and linguistic areas. They found that every language distinguishes at least three **clause types**: declaratives (1), interrogatives (2), and imperatives (3). It is surely no accident that these are the clause types orthographically marked by '.', '?', and (often) '!', respectively. Clause type is formally defined by morphosyntax, lexis, and prosody.

- (1) He just wouldn't stop whining. Bill was shot by Max. Bill, Max shot. Bill died. Max gave the Salvos a donation. *It's snowing* is a declarative sentence. Mortgage rates down at last. Dunno who did it.
- (2) Will you stop whining? Care to come along? Which came first? The chicken or the chicken nuggets? Why bother? After all, who wants to crash a convivial high by spending an hour at the sink? I shouldn't have worn those heels today, should I? He's not bad, huh? Please may I be excused? You were where on the night of eighteenth May?

- (3) Stop your bloody whining! Move it, Grandma. Be warned! Get yourself checked by someone qualified. You give me that ball, you! Nobody move! Let the Games begin. Let me help. Let's eat. Have a good day!

The western classical tradition in linguistics identifies three **moods**: indicative, subjunctive, imperative – which partially correspond to clause types. Protagoras (490–420 BCE, Diogenes Laertius, Book IX) splits the indicative into interrogative [erōtēsis] and declarative [apokrisis]. Palmer (2001) recognizes only two moods: indicative and subjunctive, which he compares with the realis-irrealis division proposed for some Native American languages (Chafe, 1995; Mithun, 1995) and Papuan languages (Roberts, 1990); and also with the assertive/non-assertive division proposed by Quirk, Greenbaum *et al.* (1985), Wierzbicka (1988), and Lunn (1995). Cross linguistically, there is a cline between indicative/realis/assertive at one pole and subjunctive/hypothetical/irrealis/uncertain at the other (Givón, 1994; Wehmeier, 2004).

The semantics of a clause type is its **primary illocution** (PI). All languages have a **declarative** as the most frequent and least marked clause type; here its PI is symbolized **T**, because its token potentially bears a truth value when used by a speaker in an utterance in a certain context (*see Type versus Token*). The declarative is typically realis (though it may include a hypothetical). At the opposite extreme is the **PI H**, characteristic of hypotheticals, counterfactuals, intentionals, traditional subjunctives, and other irrealities. Like the subjunctive (Givón, 1994: 277; Jespersen, 1958: 318), hypotheticals often have no unique morphology. Between the extremes of **T** and **H** are strung interrogatives, imperatives, negatives, futures, and habituales which may align with **T** or with **H**. For instance, 'Jim is not here' describes an event that can be seen as a factual statement having a truth value; and therefore aligned with **T**; alternatively, it is a counterfact aligned with **H**. A question 'Who is that?' has no truth value (*It is true that who is that), thus it can align with **H**; but in the Western classical tradition it is indicative and aligned with **T**. In the space here, it is unrealistic to force all languages into a universal mold any more specific than that already described; so the focus is on English.

Coincidence between clause type and illocutionary force may have been recognized by Protagoras, certainly by Apollonius Dyscolus (100 CE); cf. Householder (1981); Sanctius (1585); Lancelot (1644); Lane (1700); Whitney (1888); Sadock (1974); Van Valin and LaPolla (1997); and Huddleston and Pullum (2002).

How does illocutionary force enter the picture?

- Linguistics is concerned (*inter alia*) with utterances in which Speaker uses a language expression and thereby performs a locutionary act; to do so, Speaker uses an identifiable sentence or clause fragment from a language *L* (sentence type, intonation type, etc.). The resulting token is a locution.
- Producing the locution demands that Speaker has knowledge of the morphosyntax, lexicon, semantics, and phonology of the language used. Recognizing the locution demands that Hearer has comparable knowledge.
- A locution will normally bear more than one illocutionary force (e.g., 'I'll see you at 10' is a statement, prediction, (potentially) commissive); yet, it will usually have only one message to convey (depending on context, perhaps a promise or a threat). The illocutionary force that carries this message is called the illocutionary point of the utterance.
- The form of the locution in the utterance must be the starting point for Hearer's interpretation of the utterance meaning. Thus, Hearer must seek to recognize (a) the locution, including the sense of each clause; (b) what Speaker intends the locution to refer to; and (c) the illocutionary forces within the utterance that give rise to its illocutionary point. Hearer hears the locution, recognizes its sense, looks to the context to figure out the apparent reference, and then seeks to infer Speaker's illocutionary intention.
- Speaker's illocutionary intention is to have Hearer recognize the illocutionary point of Speaker's utterance in order to achieve a particular perlocutionary effect – the behavioral and/or cognitive and/or emotional response to the illocutionary forces in the utterance. Speaker's perlocutionary act is an act of achieving a particular perlocutionary effect on Hearer as a result of Hearer recognizing (what s/he takes to be) the locution and illocutionary forces in Speaker's utterance.
- Recognizing the clause type is the first step toward discovering the illocutionary point via the PI. It is important to reaffirm that the PI is the semantic property of the clause type (details are given shortly). The PI of 'I'll see you at 10' is a statement (with its potential truth value); the statement makes a prediction about the Speaker's future behavior which, entering the pragmatic domain, typically constitutes a commissive; in turn, this commissive may be a promise or a threat depending on several contextual factors. The PI is one semantic basis for the pragmatic inferencing that leads to the illocutionary point.

What criteria identify clause type? Word order distinguishes declarative 'He is tall' from interrogative 'Is he tall?' Morphosyntactic marking distinguishes

the hypothetical backshifted modal in the temporally non-past ‘**Could** you mail this letter for me?’ from the indicative ‘**Can** you mail this letter for me?’, and these two interrogatives from the declarative ‘I can certainly mail it for you.’ Intonation distinguishes declarative from interrogative versions of ‘John’s gone to New York(./?)’ Similarly, in other languages: In Navajo, the imperative has the same morphosyntax as the declarative, but is prosodically distinct; in Korean, declarative, interrogative, imperative, and propositive (‘let’s’ constructions) are formally identical in intimate and polite speech levels, but are distinguished by prosody. In addition to prosodic marking, the interrogative ‘John’s gone where?’ is lexically marked by the *wh*- word at the questioned location. Lexical marking is significant in identifying interrogatives in subordinate clauses: ‘She asked **how/ whether / if** John had traveled to New York.’

Many (uttered) subsentences (clause fragments whose missing constituents are recoverable from context) clearly function like well-established clause types. It is prosody (or its typographic counterpart) that distinguishes interrogative ‘John?’ [‘Is that you?'] and imperative ‘JOHN!’ [‘Come in at once!'] from each other and from declaratives. An utterance of the name ‘John’ in answer to ‘Who’s that?’ must be judged declarative on prosodic and contextual grounds. The clipped clause ‘If only!’ is judged hypothetical on lexical and perhaps also contextual grounds. Such subsentences seem intuitively to function like distinct clause types and to have distinct PIs.

The primary illocution of a **declarative**, the default clause type, is defined in Table 1 below. In the definition the precondition (‘preparatory condition,’ Austin, 1975) establishes proper grounds for uttering a declarative clause. The illocutionary intention of a declarative arises directly from Speaker’s use of it,

given the precondition. As its primary illocution, the declarative performs an act of saying that Φ . The fact that declaratives (potentially) have truth values is the principal way to positively identify them. A declarative illocution is the primary illocution and not the illocutionary point of an utterance. There are few illocutionary points that cannot be achieved using a declarative: e.g., declaratives ‘I’m asking what your name is,’ ‘I’m telling you to stop making that noise’ issue directives. Performatives such as ‘I promise to be good,’ ‘You are prohibited from smoking’ also have the primary illocution of a declarative.

The PI of **interrogatives** is exemplified in Table 2. The purported option for the Hearer to refuse or plead inability to comply distinguishes interrogatives from imperatives – which purportedly offer no such option. These different options are what make interrogatives (askings) ‘more polite’ than imperatives (tellings) – but the pragmatics of the comparative uses of interrogatives and imperatives are too complex to be adequately discussed here.

Imperatives have the PI as shown in Table 3. Many imperative clauses are entreaties; they include supplications to someone powerful or wronged (‘Forgive me’), propositives (‘Let’s eat’), and instructions which are of primary benefit to Hearer (‘Have a nice day!’). Cross linguistically, first and third person ‘imperatives,’ often called ‘jussives,’ are frequently subjunctive (Palmer, 2001).

English has two independent **hypothetical** constructions that contrast with the three major clause types (see Table 4). Otherwise, in English, hypotheticals occur within the scope of declaratives, interrogatives, and imperatives, whose prosody they adopt along with their values. Hypotheticals may occur within the scope of a declarative, *T*, such that they

Table 1 The declarative PI

<form>	T [Φ], see (1). The typical prosody involves downdrift.
<description>	Speaker says that Φ . (Declaratives potentially have truth values.)
<precondition>	Speaker has reason to believe that Φ .
<illocutionary intention>	Speaker reflexively intends the utterance of the clause to be recognized as a reason for Hearer to believe that Φ . (Notice Speaker’s purported commitment to the truth of what is being said.)

Table 2 The interrogative PI

<form>	Q [Φ]. Lexical markers such as post clausal English ‘eh?’, clause final Japanese ‘ka’, English ‘wh’- words, ‘if’ and ‘whether’ in subordinate clauses, and/or morphosyntactic markers such as subject-auxiliary inversion in main clauses. Because rising intonation typically marks orientation toward Hearer, interrogatives typically display updrift.
<description>	Speaker asks Hearer something—makes a request (cf. Allan, 1986; questions are requests for information to be delivered verbally). There is a purported option for the Hearer to refuse (or plead inability) to comply.
<precondition>	Speaker purportedly believes that Hearer can or might be able to respond appropriately to what is asked in the clause.
<illocutionary intention>	Speaker reflexively intends the utterance of the clause to be taken as asking Hearer something.

(potentially) have truth values within some hypothetical world; for example, the complement of a verb of wishing. In T[I wish H[I were rich]], the 'were' is backshifted, i.e., looks like a past tense, but is in fact the nonpast derived from Old English subjunctive 'wære' (past tense would be 'I wish(ed) I **had been** rich'). In conditional I[H[If Harry should call]], tell him 'No', the protasis invokes a hypothetical world; the apodosis is imperative and supplies the PI. Within interrogatives, Q[H[Φ]], ('Could you mail this for me?'), the hypothetical is marked by one of four backshifted modals: 'could,' 'might,' 'should,' 'would.' What is here called *hypothetical* is often referred to as *subjunctive mood*; but the fact that it occurs within the scope of other moods makes this classification problematic—at least for those who wish to retain traditional definitions of mood.

Expressives are not traditionally recognized as a clause type because none are full syntactic clauses, e.g., 'Goodness gracious!' 'Wow!' 'Jesus!' 'Thanks.' 'Congratulations.' 'Hi.' 'Bye.' 'Good luck!' They can be distinguished on semantic and lexical-cum-morphosyntactic grounds; they are short and usually verbless. Like clauses, they can stand alone in expressing a complete thought. They are **idioms**, often with idiomatic counterparts in other languages. They do not admit passivization or negation. Expressives do not have truth values, so they are not declaratives; they do not make requests, so they are not interrogatives; they do not direct or entreat, so they are not imperatives. Some are subjunctive. Their principal function is to display a sometimes perfunctory, sometimes strongly felt emotive reaction or social interaction toward something that has occurred. One subset of them will serve to illustrate all.

'Thanks' is presumably foreclipped from 'I offer you my thanks.' However, one can't willy-nilly strip out the possessed noun from a string 'I offer (you) my NOUN' to create a synonymous utterance. The monosyllable 'Book' could, in a well-defined context such as proffering the book, be interpreted as 'I offer you my book'; but this not the kind of condition applicable to 'Thanks.' Furthermore one cannot foreclip 'I offer you my help' to create the monosyllable 'Help', which is imperative. Apparently, utterances with an expressive illocutionary point facilitate the creation of brief idiomatic counterparts for ritualized behavior and to satisfy the constraints on verbal ejaculation. 'Thank you' is normally subjectless and idiomatic by contrast with the declarative 'I/We thank you.' It is not part of a normal paradigm: It is not imperative like 'Thank him.' It cannot be tensed: 'Thanked you' is perhaps possible as an aphetic diary entry, but not as a normal report of past behavior. Both 'Thanks' and 'Thank you' are reported like any declarative ('I thanked him') – which is normal for expressives. 'No thanks' and 'No thank you' are idiomatizations of two separate subsentences ('No, thanks' / 'thank you') from which the disjuncture has disappeared. 'Thanks' and 'Thank you' mean 'I thank you'; their negation is 'I don't thank you.' This is not the meaning of 'No thanks' / 'thank you' which are explicit rejections of an offer; just as 'Yes, thanks' is an acceptance.

Exclamatives occur within the other clause types and do not count as a distinct clause type in their own right (despite the way they are discussed here). Exclamatives are all prosodically marked by exaggerated acoustic intensity (wide-ranging peaks and troughs) that is indicated orthographically by an exclamation mark, '!', and there is lexical marking of some

Table 3 The imperative PI

<form>	I[F[Φ]]. Prosodic marking: falling intonation. Imperatives occur only in independent clauses (including coordinate and appositive clauses). The verb is in the base form and non-past tense, but semantically future (F).
<description>	Speaker directs or entreats Hearer to do A. The direction or entreaty is present time, the act A is future – though often expected to start immediately. There is purportedly no option for the Hearer to refuse (or plead inability) to comply.
<precondition>	Speaker purportedly believes that Hearer can do A.
<illocutionary intention>	Speaker reflexively intends Hearer to take the utterance of the clause as a reason to do A.

Table 4 The hypothetical PI

<form>	H[Φ] where Φ is either 'Would that S' (e.g., 'Would that I were rich') or 'May S' ('May he rot in hell!') in which 'Would' and 'May' are main verbs using the root senses of these modals, and in which neither 'Would' nor 'May' can be negated.
<description>	Speaker vehemently wishes (hence the root senses) that the proposition in S may (or may have) come about in some hypothetical world accessible from the real world in which the utterance takes place.
<precondition>	Speaker has some reason to wish that S may (or may have) come about.
<illocutionary intention>	Speaker reflexively intends the clause to be taken as a reason for Hearer to believe that Speaker vehemently wishes that S may (or may have) come about in some hypothetical world.

declarative exclamatives by clause initial ‘how’ and ‘what’ immediately followed by the preposed clause constituent in the focus of exclamation (‘What a bloody whiner he was!’ ‘How she hated it!’). Speaker expresses within Φ a forcible, emphatic, or vehement point of approbation, delight, pleasure, pain, surprise, anger, irritation, etc.; the reflexive-intention is to focus Hearer’s attention on a part of what is being said in Φ as being of particular importance in the context of the communication in progress; but this is just a modification on the PI of the governing clause type. The same might be said of hypotheticals when they do not contrast with the other clause types, which is one reason to deny that there is a subjunctive mood in English.

Primary illocution (PI) is the semantics of clause type or corresponding subsentence. Declarative, interrogative, imperative, subjunctive, expressive, exclamative clause types or subsentences are identified through morphosyntactic, lexical, and prosodic form, their use in main and subordinate clauses, and behavior under negation. The PI is identified with Speaker’s illocutionary intention in using the clause type/subsentence. This PI is the starting point for Hearer inferring the illocutionary point of (Speaker’s message in) the utterance containing the clause, in the manner first described in Searle (1975) (see also Bach and Harnish, 1979; Allan, 1986, 2001). It is probable that all languages have most of the clause types/subsentences described here. Further research is needed to systematically accommodate conditionals, imperatives, jussives, laudatives, obligatives, optatives, prohibitives, propositives, and purposives within the network of relations manifest by clause types and illocutionary forces. Exactly how all these are to be related to the traditional category of mood remains to be seen.

Natural Kind Terms

S Gross, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Natural kind terms denote, or purport to denote, natural kinds – for example, physical, chemical, and biological kinds. They are of particular interest to philosophers concerned with what enables us to think and talk about natural kinds. According to *descriptivism*, the denotation of natural kind terms is determined by an associated description. According to *causal theories*, the denotation is determined by language users' causal interactions with exemplars. Hybrid views are also espoused. These positions parallel those taken on the denotation of proper names (cf. Stanley, 1997; see **Proper Names: Philosophical Aspects**).

Debates about natural kind terms carry implications for a variety of philosophical issues. Causal theories, for example, are *prima facie* in tension with a methodological individualism that assumes that cognitive properties – including the semantic properties of an individual's terms – are determined by properties intrinsic to the individual (cf. Burge, 1979). Discussions of natural kind terms also intersect with debates in cognitive psychology concerning tacit essentialism (cf. Gelman, 2003) and with discussions in the philosophy of science concerning the bases for successful inductive generalization (cf. Kornblith, 1993).

What Are Natural Kind Terms?

Human first languages do not syntactically or morphologically mark natural kind terms as such. Natural kind terms are distinguished solely by the kind of kinds they purport to denote. What then are natural kinds? The core idea is that they are object groupings that reflect real distinctions in nature – in particular, distinctions that play an explanatory role in (accurate) scientific theories. Natural kinds are contrasted with arbitrary groupings of objects whose behavior cannot be explained by shared fundamental

properties – for example, the kind comprising Plato's left ear, the natural numbers, and the shoes owned by current heads-of-state. Natural kinds are also contrasted with conventional groupings that reflect practical human concerns, such as the citizens of Pennsylvania. Relatedly, they are contrasted with artifactual kinds – objects grouped together in virtue of our intending them to fulfill certain functions, such as tables. Natural kind terms thus arguably include 'gold,' 'tiger,' and 'H₂O'; but not 'keys' or 'gorks' (where it is hereby stipulated that something is a gork if and only if it is Plato's left ear, a natural number, or a shoe owned by a current head-of-state).

This basic characterization leaves much room for disagreement about just which terms are natural kind terms. First, it admits adjectives – at least those that denote groupings that reflect real distinctions in nature (perhaps 'red' but not 'cultural' – cf. Kripke, 1972). But on some views, not all groupings are kinds, and so not all terms for them are kind terms. Many restrict kind terms to nouns or noun phrases that admit a generic reading, accept kind-level predicates like 'are widespread,' and are associated with criteria of individuation. These terms may be either mass or count nouns (cf. Carlson, 1991).

Second, there are disagreements about various further theses concerning natural kinds and, as a result, disagreements about which kind terms are natural kind terms. Some maintain, for example, that instances of a natural kind share an unchanging essence, that natural kinds fall into a non-cross-classifying hierarchy, or that natural kinds have no borderline instances. On such bases, they argue against the inclusion of various candidate kinds – and thus against the inclusion of various candidate kind *terms*. Debates concerning biological species and terms for them are a prominent example (cf. Dupré, 1981; LaPorte, 2004). (Philosophers debate many other issues concerning natural kinds, not all of which affect the classification of natural kind *terms*. For example, they disagree about whether natural kinds have reality independent of our categorizations and about what sorts of entities they are: sets, properties, complex individuals, or something *sui generis*.)

Third, the use of many putative kind terms seems sensitive to human interests. It may seem that we have discovered that the denotation of ‘water’ is shared by ‘H₂O.’ But the uses of ‘water’ and of ‘H₂O’ are sensitive to amounts and kinds of impurities in differing ways. We would hesitate to call tea ‘water’ but not the stuff flowing in a river, even though the latter might have more impurities vis-à-vis H₂O than the former. However, neither tea nor a contaminated river is H₂O. Some conclude that ‘water’ is not a natural kind term, while others argue that such phenomena can be explained pragmatically (cf. Malt, 1994; Braisby *et al.*, 1996; Abbott, 1997).

The Semantics of Natural Kind Terms: Descriptivism

We may distinguish three questions concerning the semantics of natural kind terms:

1. the *property* question: what are the semantic properties of natural kind terms?
2. the *foundational* question: in virtue of what do natural kind terms have these semantic properties?
3. the *competence* question: what is required for a speaker to grasp the semantic properties of natural kind terms?

The past 30 years of debate have been shaped to a large extent by Kripke’s (1972) and Putnam’s (1975) attacks on *descriptivism*. Classic descriptivism maintains three theses corresponding to these three questions. According to *property descriptivism*, the semantic properties of a natural kind term are those of some definite description. According to *foundational descriptivism*, a natural kind term has a particular semantic property – its denotation – in virtue of its relation to such a description. According to *competence descriptivism*, a speaker understands a term in virtue of associating it, explicitly or tacitly, with such a description.

Forms of descriptivism can be further articulated in various ways. For example, John Locke (1979: Book III, Chapter VI) – a *locus classicus* of descriptivism – in effect required that the relevant descriptions be constructed from observational terms. This is because his descriptivism is in service to his developmental and epistemological empiricism, according to which mental states arise from and are justified by experience. Locke distinguished the ‘real essence’ and the ‘nominal essence’ of substances, such as gold. The real essence is what makes gold what it is. Locke was pessimistic that we could ever discover a substance’s real essence. The nominal essence is the list of observable properties that a speaker associates with the term for this substance. Locke held that the term ‘gold’ signifies

an “abstract idea” composed of ideas of these observable properties (shiny, yellow, malleable, etc.). A natural gloss is that the content of a natural kind term like ‘gold’ is given by and identical to an observational description such as ‘the stuff that’s shiny, yellow, malleable, etc.,’ and a speaker grasps that this is the term’s content in virtue of taking that description to define it.

Against Descriptivism

Descriptivism is a natural view since such features clearly play a role in categorization. But Kripke and Putnam raised a host of objections aimed at separating how people categorize things from what determines the denotation in fact possessed by their terms.

First, there are *modal* objections. Consider ‘gold’ and a candidate Lockean description. Arguably, the sentence ‘gold is gold’ expresses a necessary truth – as does, on at least one reading, ‘the shiny, yellow (etc.) stuff is the shiny, yellow (etc.) stuff.’ But ‘gold is the shiny, yellow (etc.) stuff’ does not. For it is metaphysically possible both that there be stuff that possesses those observable properties but differs from gold in some fundamental way and that there be gold lacking some one of those properties. Relatedly, ‘it’s necessary that gold is gold’ expresses a truth, but ‘it’s necessary that gold is shiny, yellow, etc.’ does not. (It is thus often maintained that natural kind terms are rigid designators [see **Rigid Designation**], although how best to extend the concept beyond proper names is not obvious and depends on what one takes a kind to be; cf. Soames, 2002.)

A second, *epistemic* objection is that the descriptions associated with natural kind terms may be false without affecting the natural kind term’s denotation. Suppose that I falsely believe that tigers are the fastest cat and that this is a fundamental, defining characteristic of tigers. It does not follow that, when I use the word ‘tiger,’ I in fact denote cheetahs. More generally, one might reject a view according to which, as scientists revise their core beliefs in the light of new research, the denotation of their terms changes, so that scientists adopting different theories become communicatively isolated behind incommensurable vocabulary.

Finally, the *absence* objection points out that speakers competent in the use of a natural kind term often do not associate any particular description with it at all – or at least none that the speakers themselves would consider especially relevant semantically or that would uniquely pick out the natural kind at issue. Putnam (1975) notes that what he happens to know of beeches basically coincides with what he happens to know of elms, so he has available no

descriptions that would account for the distinct denotations of ‘beech’ and ‘elm.’ Further, even if there are descriptions that uniquely pick out these kinds, it is far from obvious that they play any role in a speaker’s cognitive economy.

Causal Theories

Rejecting descriptivism allows one to recognize the possibility of misalignment between what one’s terms are about and how one conceives of them. But, if not one’s conception, what determines the denotation of natural kinds terms? Causal theories deriving from Kripke (1972) and Putnam (1975) endorse a two-part account of the foundational semantics of natural kind terms: the denotation of natural kind terms is fixed by appropriate causal interaction with instances of the kind and can be socially transmitted to others by patterns of linguistic deference. A natural kind term is introduced with an intention – or comes to be used with an intention – that it denote stuff relevantly similar in underlying structure to *stuff like that*. What fixes the denotation is thus something like a Lockean real essence. ‘Gold’ denotes, not the stuff that shares various observable properties, but rather the stuff that has some fundamental properties responsible for the observable ones, whatever those fundamental properties might be. People not privy to samples of such stuff intend to use the term as do those who are. The denotation of ‘beech’ in Putnam’s idiolect, for example, is fixed by the fundamental properties of the samples with which those to whom he defers have interacted. Scientific inquiry enables us to learn about these fundamental properties, but linguistic competence does not require – indeed, arguably helps make possible – such knowledge.

On such a view, what semantic properties a natural kind term has are in part determined by features external to speakers – by the (perhaps unknown) underlying nature of the ostended stuff and by features of one’s linguistic community. Kripke’s and Putnam’s foundational semantics for natural kind terms thus supports *linguistic semantic externalism* – the thesis that the semantic properties of one’s terms do not supervene on one’s intrinsic states. A particularly vivid illustration is provided by Putnam’s ‘Twin Earth’ thought experiment. Suppose that there is another planet just like ours except that, in place of water (H₂O), its lakes, oceans, swimming pools, etc., are filled with XYZ, a liquid superficially similar to water in appearance, taste, odor, etc., but with a different chemical microstructure. Since XYZ is not H₂O, it is not water but rather something that merely resembles water. Now, suppose Oscar is a denizen of Earth, and Twin Oscar is his counterpart on Twin Earth – an

exact duplicate with respect to intrinsic properties. Out of Oscar’s mouth, ‘water’ denotes water (H₂O), but not XYZ. Were it pointed out to Oscar that the liquid he just referred to as ‘water’ was in fact made up of completely different stuff, he would admit that he’d been misled by its superficial resemblance to water. Out of Twin Oscar’s mouth, ‘water’ denotes XYZ (that is, what *they* call ‘water’ on Twin Earth), but not water – for parallel reasons. But Oscar and Twin Oscar are intrinsically identical. Therefore, their words’ semantic properties are a function, not just of their intrinsic states, but also of external factors. Such externalism stands in sharp contrast to, for example, Chomsky’s internalist conception of language (see *E-Language versus I-Language*).

Descriptivism Redux

Descriptivists have defended themselves both by replying to Kripke’s and Putnam’s objections and by raising problems for causal theories.

In reply to the *modal* argument, one finds four objections, presented here in increasing order of concessiveness. Some reject the very idea of metaphysical modalities. Others reject the intuitions behind the particular modal claims made, sometimes adding that such intuitions are sensitive to framing effects (and might not be cross-culturally robust – cf. Machery *et al.*, 2004). Then there are those who deny that critics have considered the *right* descriptions: if ‘gold’ is associated with a *rigidified* description such as ‘what’s actually the most precious yellow metal,’ the modal argument is blocked. Finally, some point out that the argument, if successful, applies only against *property* descriptivism and so does not yet pose a problem for strictly *foundational* descriptivists.

In reply to the *epistemic* objection, a descriptivist might likewise complain that causal theorists focus on the wrong descriptions. There must be *some* accurate description that can be associated with the natural kind term. For instance, the relevant description could be constructed from the causal theorist’s account of the determination of natural kind terms’ denotation: ‘the stuff that (actually) stands in such-and-such causal relations to users of the term K.’ It may be objected that speakers can be competent in the use of natural kind terms despite not associating them with such theoretically sophisticated descriptions. We return to this sort of objection presently. But there are also less theoretically sophisticated candidate descriptions, such as ‘the stuff that’s (actually) relevantly like *this* stuff, or the stuff others have talked about’ (so long as there is no bar on demonstratives), or on some views ‘the stuff that’s called water in this language’ (cf. Haas-Spohn, 1997).

In reply to the *absence* objection, a descriptivist might posit tacit knowledge of the description's bearing on the natural kind term. That is, the descriptivist might hypothesize that the mind or brain associates natural kind terms with such descriptions, even though a speaker is not necessarily aware of this. Alternatively, a descriptivist might argue that such descriptions can play the role required by *property* and/or *foundational* descriptivism despite speakers' ignorance of them. Rather than positing tacit knowledge, the descriptivist might then abandon *competence* descriptivism altogether. This might appeal in particular to those who deny that a semantic theory must also play a role in an account of semantic competence. According to such theorists, the task of semantics is to characterize the semantic properties of expressions, not to explain how speakers grasp those properties (cf. Katz, 2004).

In addition to replying to causal theorists' objections, descriptivists emphasize that causal theories face *prima facie* problems of their own. First, it is not obvious how causal theories should accommodate apparently denotationless natural kind terms such as 'phlogiston' and 'unicorn' (see **Empty Names**). These terms are not synonymous. But it is unclear how a causal theorist can distinguish them semantically, since the theorist cannot appeal to a difference in denotation. Descriptivists face no problem here, since they can associate such terms with nonsynonymous descriptions ('the stuff flammable material gives off in combustion'; 'the horse-like mammal with a magical horn').

Moreover, causal theorists face the *prima facie* problem that, on their view, 'phlogiston' is not a denotationless term after all, since it was introduced via interaction with instances of combustion and thus arguably denotes *oxygen*, the stuff in fact responsible for the observed behavior. Unless they can resist this consequence, causal theorists would be committed to a history of science according to which phlogiston theorists were correct that phlogiston exists but simply wrong that it comes from the flammable material.

Finally, an object can be an instance of various natural kinds. If my use of 'gold' is associated with exemplars that are not only Au but also all instances of a particular isotope, what determines to which kind my term refers? Perhaps indeed the term should denote *metals*. This is an instance of the *qua*-problem (anticipated by Locke – cf. Stanford, 1998): it is unclear of what kinds the instances are exemplars, in particular whether we are to consider the instance *qua* gold, *qua* metal, *qua* a certain isotope, etc. Here too it can seem that the foundational semantics requires a constraining descriptive component.

Hybrid Views

In part for these reasons, some have developed hybrid views. There are two not mutually exclusive ways one can combine a moderate descriptivism with a causal theory – both of which have antecedents in Putnam (1975). First, some defend a limited *property* descriptivism while abandoning the claim that the denotation of natural kind terms is determined solely by such descriptions. The idea is that among the semantic properties of a natural kind term is an associated description (or a meaning with description-like content), even though the denotation is not determined by this description and might not align with its extension. Second, some maintain that a natural kind term's denotation is determined by causal relations to exemplars as constrained by some descriptively characterized requirement. It is not sufficient to say that a natural kind term denotes *stuff like that*: it must be stuff that is *relevantly similar* to the exemplar in ways that require at least some descriptive elaboration (cf. Stanford and Kitcher, 2000).

Neodescriptivists have attempted to absorb the insights of causal theories in other ways as well. We have already noted that one might include rigidifying and/or demonstrative expressions in the descriptions. In addition, some theorists distinguish two dimensions of semantic content: a description-like first intension and a second intension that, in the case of natural kind terms, is a function of the first intension and the actual environment of the speaker. The first intension determines a classically descriptivist extension. The second intension, however, does not determine an extension on its own at all; it constrains an extension that is in part determined by how the world in fact is (cf. Chalmers, 2002; see **Two-Dimensional Semantics**).

Natural versus Nonnatural Meaning

A Barber, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

Grice's Distinction

H. P. Grice noticed a potentially confusing lexical ambiguity in the word 'means' (see Grice, 1957). Contrast claim (1) with claim (2):

- (1) The flooded river means that the mountain snow is melting
- (2) The sentence 'La neige des montagnes fond' means that the mountain snow is melting

If it turned out that the mountain snow was not melting, then claim (1) would have to be withdrawn, whereas claim (2) would not. The French sentence in (2) would mean what it does even if it was untrue. Grice distinguishes what he calls natural meaning, which is what 'means' means in the context of a claim such as (1), from nonnatural meaning, invoked in (2). He offers a range of criteria for distinguishing the two kinds of meaning – 'meaning_N' and 'meaning_{NN}' as he abbreviates them – but the key difference is sometimes put in terms of meaning_N, unlike

meaning_{NN}, being *factive*: what is meant_N can only be a fact, whereas what is meant_{NN} need not.

Sentences are not the only kind of entity that may be said to have meaning_{NN}. Others include people, as when we say that so-and-so meant something; utterances of a sentence as opposed to the sentence itself; and mental states, such as beliefs, which have representational content without necessarily representing accurately. The distinction seems to be available no matter what one takes to be the primary bearers of meaning_{NN}.

Grice stressed this distinction because he was interested in nonnatural meaning, which he deemed to be harder to pin down and so more in need of investigation than natural meaning. Natural meaning is simply a relation of necessitation between one event and another, for example a causal relation such as the one alleged in (1). The investigation of nonnatural meaning is handicapped, he felt, by confusions that arise through failure to see the distinction between it and meaning_N. In his 1957 paper, he criticizes the attempt to understand meaning_{NN} in terms of meaning_N, and then appeals to the distinction in the course of blocking objections to his own theory of meaning_{NN}.

Grice's Theory of Non-natural Meaning

Grice's distinction is acknowledged even by those who do not endorse his theory of meaning_{NN}. But this latter has been influential nonetheless (see Schiffer, 1972 for a development of it, and Schiffer, 1987 for a retraction). The meaning_{NN} of an act, he suggests, turns entirely on the intention of its agent. Not all acts have meaning_{NN}, but those that do are performed with a triplex of intentions. First, the agent intends to bring about an effect of some kind in the mind of her audience – a change of belief, for example. Second, she intends to be recognized by this audience as having this first intention. Third, she intends the effect to arise *through* this recognition. If an act is performed with intentions of this form, then the intended effect is said by Grice to be the act's meaning_{NN} (or, equivalently, it is what the agent meant_{NN} by the act; or again, it is what the expression used means_{NN} on that occasion).

In practice, recognition of the intention is usually achievable only because of the close association between acts typed according to whether they share the same meaning_{NN} and acts typed according to an overt, recognizable pattern. In the linguistic case, for example, typing according to the sentence uttered will usually group together utterances with the same meaning_{NN}. Shared knowledge of which sentences are paired with which meanings_{NN} is what makes individual acts of meaning_{NN} possible in the first place. This leads Grice to introduce a derivative notion, timeless meaning_{NN}, which is the meaning associated with the repeated use of a particular pattern. Sometimes this timeless meaning_{NN} of a sentence is distinct from the meaning_{NN} of an utterance of it on an occasion. Someone could use the sentence *I know where you live* to mean_{NN} something distinct from what it timelessly means_{NN}. It is no coincidence that Grice was among the first to notice and develop a theory of the phenomenon of implicature (see Grice, 1975).

Other Remarks

Though the existence of a distinction between natural and nonnatural meaning is clear once pointed out, it is easy to become confused over its precise nature. After all, utterances are events and, as such, have meaning_N as well as meaning_{NN}. And (3) is true on both readings of 'means':

- (3) The canyon-dweller's shout of "Here comes an echo" meant that we would shortly hear an echo

Moreover, the utterances of an omniscient truth-teller – God, for example – mean_N whatever they mean_{NN}. Efforts by philosophers of mind and language in the 1980s to understand systems of representation naturalistically (see Millikan, 1984; Dretske, 1988) may shed light on these cases. A distinction is sometimes drawn between what an instance of mental representation *R* *indicates* and what it *represents*. What it indicates (or what information it carries) is understood entirely in terms of the causal relations instances of *R* tend to enter into – something like meaning_N. It represents not what it indicates but *what it is the function* of instances of *R* to indicate, within the representational system as a whole. So when the representation system, i.e. the mind or some part of it, is functioning properly, an instance of *R* will indicate what it represents. Misrepresentation is a matter of functional breakdown in the system, resulting in instances of *R* that fail to indicate what they represent, i.e., what it is their function to indicate. An omniscient truth-teller can be thought of as a properly functioning representational system, which is why God's utterances mean_N (or indicate) what they mean_{NN} (or represent).

Naturalism

J Kulvicki, Dartmouth College, Hanover, NH, USA

© 2006 Elsevier Ltd. All rights reserved.

Philosophical naturalism is the view that traditional problems in epistemology, language, metaphysics, mind, and morality can be solved only by appeal to the methods and results of empirical research. We cannot hope to solve these problems *a priori*, by reflecting on our everyday concepts and the logical relations between them. On the face of it, naturalism seems quite appealing, and almost obvious. No one thinks we can figure out how the sun works without investigating the matter empirically. Why would we think philosophy's Big Problems will not yield to science's prying eyes?

Naturalism is controversial because many of these topics are, broadly speaking, normative. The empirical sciences describe, but they do not prescribe: they have little to say about how the world *should* be. As a result, the sciences leave out precisely the normative aspects that make these phenomena so interesting, valuable, and puzzling. Naturalists take up this challenge in radical and moderate forms. Moderates try to fit norms into the natural world by explicating the conditions for satisfying a norm in nonnormative, scientifically informed terms. Radicals refuse norms altogether. Normative inquiry is a lost cause, say the radicals, so it should be abandoned in favor of purely descriptive endeavors.

Epistemology asks what knowledge is and how we should go about getting it. What makes certain methods for learning the truth reliable? Under what conditions are we justified in believing something? Naturalized epistemology treats these as scientific questions. We need to know how our perceptual systems work, how we reason, and how we make decisions in order to evaluate competing approaches to learning. The psychological and brain sciences thus become relevant to the theory of knowledge. In the last century Willard v. O. Quine, a radical, is considered the father of naturalized epistemology (1969). Moderates, such as David Armstrong (1961), Alvin Goldman (1967), and Fred Dretske (1968, 1981), were influential in making science part of the solution to the problems of knowledge. Kornblith (1994) provided a nice collection of essays on naturalizing epistemology, and Kitcher (1992) provided a valuable discussion of naturalism's history and current place in epistemology.

By contrast, H. H. Price claimed that “[e]mpirical science can never be more trustworthy than perception, upon which it is based. . .” (1932: 1). Price and the other sense datum theorists of the first half of the

20th century argued that since knowing the results of science depends on perceiving the world, we cannot use the science of perception as a guide to epistemology. They were naturalists in that they sought to explain knowledge in terms of what we sense and what we cannot in fact doubt, the latter being non-normative notions (cf. Kim, 1993). They were not naturalists, in that they thought we must first secure foundations for perceptual knowledge before we can trust science as a tool for furthering or improving it. Epistemology thus becomes an *a priori* endeavor. The sense datum theorists in particular sought that which we cannot doubt – for Bertrand Russell it was “facts of sense (i.e., of *our own* sense-data) and the laws of logic” (1914: 119) – and tried to show how to build further knowledge thereupon by logical construction. This program culminated in Rudolf Carnap's *Der Logische Aufbau der Welt* (1928), an impressive but failed effort, at least given general opinion.

Quine insisted that “it is within science itself, and not in some prior philosophy, that reality is to be identified and described” (1981: 21). A radical naturalist, Quine saw epistemology as a purely descriptive, nonnormative enterprise that asks how we in fact go about acquiring beliefs and knowledge about the world (Kim, 1993).

If we are out simply to understand the link between observation and science, we are well advised to use any available information, including that provided by the very science whose link with observation we are trying to understand. (Quine, 1969: 76)

Quine's influential ‘Two dogmas of empiricism’ (1951) provided the groundwork for this view. First he denied that all our knowledge derives from a privileged class of claims about, for example, what we sense. The sense datum theorists thought that claims about what we sense are individually indubitable. From these special claims, we derive the rest of our knowledge. Quine, by contrast, thought that there is no special class of individually confirmed claims. Claims are not confirmed one by one but *en bloc*. “Our statements about the external world face the tribunal of sense experience not individually but only as a corporate body” (Quine, 1951: 43). If this is so, we would do well to bring the results of science into the discussion of what knowledge is and how we actually go about getting it. Quine believed, after all, that the senses provide us with all the information we can get about the world, but he saw this as a result of scientific research, not a claim prior to science. Second, Quine (1951, 1954) rejected the idea that any claims are analytic, or true just in virtue of their meaning and not in virtue of whether they fit with

observation (see also Burge, 1992: 6–9). Statements that seem to be true just in virtue of their meaning, and even Russell's 'laws of logic,' are not in principle immune to disconfirmation any more than ordinary empirical claims, so there is little reason to exclude the latter from one's account of knowledge.

Quine was criticized for straying from his naturalistic scruples when it came to language. Based partly on worries about language acquisition, Quine argued in favor of two theses: the indeterminacy of translation (1960) and the inscrutability of reference (1960, 1970). According to the former, there is no fact of the matter about which translation among competing translations of a given language into another is correct. The claim is not that it is rather difficult to be sure one has achieved the proper translation but that there is no fact of the matter about which is correct at all. The latter thesis claims that there is no fact of the matter about what specific terms in a language refer to. Taken together, these theses led Quine to a general skepticism about meaning and reference.

Chomsky (1968, 1975, 1980) objected to Quine's theses on the simple grounds that they contradicted Quine's claims about every other science. Just about everyone has agreed that the empirical evidence underdetermines one's theory of a phenomenon. So, indefinitely many theories can account for any given set of evidence. This does not interfere with science's progress, and it is not clear why the study of language should answer to a higher standard than the other sciences.

If the underdetermination of physical theory by evidence does not lead us to abandon the 'realistic point of view' [...] then the comparable underdetermination of grammatical theory by evidence does not support Quine's claim that there is no fact of the matter [...] to be right or wrong about . . . (Chomsky, 1975: 183)

Complaints in a similar vein can be found in Fodor and Lepore (1992: 70–82). Quine (1960: 75–6, 1968) argued that the cases are not parallel. In a remark that nicely paralleled Quine's quote (1969: 76), Robert Fogelin complained:

... Quine's attempt to trace a path from stimulation to science is carried out with almost no concern for the psychological reality of the process, that is, with almost no references to empirical investigations of how language is actually acquired. (1997: 561)

In the end, Quine's controversial claims should, by his own lights, be subject to empirical confirmation or disconfirmation. According to linguists and many philosophers, the weight of the evidence seems to be against him. Scott Soames (2003: 404–405)

suggested that Quine's views might not admit of empirical support one way or the other, which would, on Quinean grounds, render them meaningless and useless.

Naturalized philosophy of mind tries to show how facts about intentionality, consciousness, meaning, and the like can be explained in terms of what the natural sciences – particularly psychology, neuroscience, and biology – tell us about ourselves. Here, too, we find problems with normativity. For example, concepts have intentional contents. They are about things and states of affairs. What, then, makes my concept of snow about snow? Perceptual encounters with snow cause me to think of snow and have certain beliefs about it. Perhaps, then, my concept of snow has its content in virtue of what causes me to deploy it. Cleverly placed whipped cream, however, can fool me into believing that there is snow on my windowpane. Whipped cream is not snow, of course, and my snow concept is not about whipped cream at all. It cannot be just anything causing me to deploy my snow concept figures in its content. If it did, the content would be quite disjunctive – snow or whipped cream or cotton gauze at a distance, etc. – and none of my uses of the concept would be mistaken. Any naturalistic theory of content must explain how we incorrectly use concepts, and this appeals to norms regulating their application. Scientific theories tend not to appeal to norms. Attempts to naturalize content are due to Fred Dretske (1981), Ruth Millikan (1984), and Jerry Fodor (1990), among others. Burge (1992) helpfully reviewed the development of naturalized philosophy of mind and language in the 20th century (see **Representation in Language and Mind**).

Chomsky's (1980, 1995, 2000) commitment to naturalism has been 'methodological' in that he has taken scientific explanation to be the goal when we investigate language and mind. He famously denied that there is an interesting 'metaphysical' sense to naturalism according to which research aims to explain mental and linguistic phenomena in physical or biological terms. Chomsky has been skeptical of metaphysical naturalism because, first, reduction is rarely a prerequisite for conducting science. For example, biology has not been reduced to physics, but it is a science nonetheless. And second, we do not have a clear enough conception of the physical for the metaphysical project to make sense.

Lacking a concept of 'matter' or 'body' or 'the physical' we have no coherent way to formulate issues related to the 'mind-body problem' ... the sciences postulate whatever finds a place in intelligible explanatory theory, however offensive that may be to common sense. (Chomsky, 1995: 4–5)

Naturalists are committed to following science wherever it leads, but we do not understand the world well enough to make a stronger, metaphysical commitment to reducing the mind to the physical. Since our notion of what is physical is frequently in flux, it seems odd to insist that the mind must be explicable in terms of it. Responses to Chomsky's views, with replies by Chomsky, can be found in Antony and Hornstein (2003).

Biology, more than most other sciences, must deal with normative notions. What is the function of this trait? Is it adaptive? What was its original purpose? And so on. Philosophers have not missed the fact that biology offers a promising approach to the moderate naturalists' goals. Alex Rosenberg (1996: 4) suggested that "[i]f naturalism is to replace *a priori* first philosophy with scientific theory, then at least for the present the theory in question will be Darwin's." Millikan's work (1984, 1993) has focused on explicating a naturalistically acceptable notion of biological function and applying it to problems in the philosophy of mind and language. Dretske (1988), David Papineau (1993), Karen Neander (1995), and Daniel Dennett (1995), among others, have followed her lead.

Negation: Philosophical Aspects

D DeVidi, University of Waterloo, Waterloo, Ontario, Canada

Most people, if they think of negation at all, have in mind something fairly simple, namely classical (or Boolean) negation. Classical negation is an operator that works as a sort of toggle switch on propositions or predicates: When applied to a proposition with the semantic value 'True,' it returns a proposition with the semantic value 'False' and vice versa. When applied to a predicate true of some collection of individuals (of some type), it returns another predicate that is true of exactly those individuals (of that type) for which the original failed to hold. If one regards relations as predicates that apply to pairs (triples, quadruples, etc.), and considers pairs (etc.) as individuals of a higher type, one has a general-purpose notion of negation. Make the convenient assumption that every proposition has exactly one of the two truth values just mentioned, and that predicates have sharply defined domains of application and sharp boundaries within those domains, and nothing more needs to be said.

It is increasingly rare to find philosophers of logic who are happy with the idea that this is the whole story about negation. Most philosophical issues regarding negation are illuminated by considering some reasons for their dissatisfaction. However, first it is useful to consider the question of what properties an operator needs to have to count as a genuine negation. This is surely the fundamental philosophical question about negation, and it must be answered before one can adjudicate the justice of the most common complaint raised against various nonclassical negations – that they are not really negations at all.

To keep the discussion manageably brief, we gloss over some philosophical niceties. For instance, we shall move freely between negations of propositions and of predicates when it makes examples clearer, although some contend that these might not involve the same operator. We also mostly ignore the question of whether negation is an operation on sentences (and predicates) or on propositions (and properties), thereby pretending some issues are simpler than they really are. We use the symbol ' \neg ' for the negation operator.

Possible Properties of Negation

Probably the strongest opinion most people would have about negation, is that for any sentence P , P and $\neg P$ cannot both be true. If $\neg P$ is really the negation of P , then it must be incompatible with P . However, one

must remember the distinction between negations and mere contraries. For if P is ' x is white,' then ' x is black' is certainly incompatible with P – it is a contrary of P – but it is not $\neg P$. For, surely, if the x in question is orange, $\neg P$ must come out true. However, ' x is black' does not. One natural way to think about $\neg P$ is as the weakest proposition that is incompatible with P . In our example, $\neg P$ is a proposition implied by any proposition that rules out x being white, perhaps equivalent to ' x is black or x is orange or x is yellow ...,' running through all the nonwhite colors. Thinking of negation in this way, and assuming that if A is incompatible with B then also B is incompatible with A (which not everyone grants, for reasons we will not pursue), is equivalent to assuming that negation obeys the following law: A implies $\neg B$ if and only if B implies $\neg A$. (In this view, A implies $\neg B$ exactly when A is incompatible with B . If this means also that B is incompatible with A , this happens exactly when B implies $\neg A$.) This is the characteristic law of so-called 'minimal negation,' and almost all candidate negations satisfy it.

Of course, the classical negation of P is not merely the weakest proposition contrary to P (although it is that) but also satisfies many additional laws. Most significantly, $\neg P$ must be a complement of P ; that is, not only must $(P \text{ and } \neg P)$ be a logical falsehood but also $(P \text{ or } \neg P)$ must be a logical truth. That $\neg P$ satisfies the latter condition for any P is called the law of excluded middle and is close enough kin to the principle of bivalence (for any P , P gets exactly one of two truth values, and so $\neg P$ gets the other) that we can ignore the difference here. Other important principles that hold for classical negation include the four De Morgan laws: $\neg(P \text{ and } Q)$ implies $(\neg P \text{ or } \neg Q)$ and vice versa, and $\neg(P \text{ or } Q)$ implies $(\neg P \text{ and } \neg Q)$ and vice versa. The logical principle sometimes called 'explosion' is valid for classical negation: Everything follows from a contradiction (i.e., a pair $P, \neg P$). In the presence of explosion, the law of excluded middle is equivalent to the principle of double negation elimination: $\neg\neg P$ implies P , which therefore also holds for classical negation.

We can now efficiently describe the most discussed nonclassical negations. (The philosophical significance of these distinctions should become clear in later sections.) If a minimal negation also satisfies explosion, we have an 'intuitionistic negation.' On the other hand, if a minimal negation satisfies the four De Morgan laws, we have what is sometimes called 'Ockham negation.' This unfortunate name is needed because common usage has it that a 'De Morgan negation' is an Ockham negation for

which also the principle of double negation elimination holds. An 'orthonegation' is both intuitionistic and De Morgan. Classical negation is orthonegation in a logical system in which 'and' distributes over 'or' and vice versa. Nonclassical orthonegations show up in nondistributive quantum logics. Distributivity guarantees that every proposition has at most one complement, but we will ignore the differences between classical and orthonegation here.

One sometimes sees discussion of 'subminimal negation.' It is characterized by the condition that the following principle of contraposition must hold: If A implies B , then $\neg B$ implies $\neg A$. Every minimal negation satisfies this principle, but not conversely. Although most would accept that this is a necessary condition for an operator to count as a negation, it seems insufficient because there are operations in natural language that seem to be subminimal negations that are difficult to take seriously as negations. Skipping details, an example is the operation we might call 'few N ': If ' x is a fish' implies ' x has gills,' then 'Few dogs have gills' implies 'Few dogs are fish,' and similarly for any similar example, but 'few N ' looks even less like a negation than any mere contrary forming operator. Sometimes, especially in programming applications, one sees operations called 'negations' that are not even subminimal (e.g., some 'negation as failure' operators). We shall not consider these operations.

Negations, Consistency, and Paradoxes

We begin with some responses to the so-called 'semantic paradoxes,' especially the liar paradox. Consider (L):

(L): L is false.

(L) certainly looks to be true if and only if it is false. Nonclassical negations often appear in proposed solutions to such paradoxes; we briefly consider a simple example later. For now, we consider so-called 'dialetheism.' Dialetheists hold that some sentences P are both true and false (and so that both P and $\neg P$ are true, if $\neg P$ is true whenever P is false). Sentences such as (L) are their prime candidates for this status. In barest outline, they argue that a century of intense effort aimed at explaining what is going on with (L) while preserving consistency has led, at best, to solutions that are plausible only to those who formulate them. The mistake, they suggest, is in trying to preserve consistency.

One obvious objection to dialetheism is that if P and $\neg P$ can both be true at the same time, the \neg symbol is not functioning as a negation. In such a case, $\neg P$ is not even a contrary of P , violating the most basic intuition

about negation. One dialetheist response is that in many dialetheic logics, $\neg(P \text{ and } \neg P)$ is a necessary truth for all P , even those where P is both true and false. They suggest that this captures the truth behind the idea that negations are contraries. It is just a surprising development that $(P \text{ and } \neg P)$ is also true in some cases.

Dialetheist must defend a negation for which explosion is not valid, on pain of holding that all statements are true. Others defend nonexplosive logics, called 'paraconsistent' logics, for a variety of other reasons. For instance, correct reasoning from a set of beliefs seems to be quite constrained, despite the fact that most sets of beliefs are inconsistent. However, if explosion were valid, correct reasoning from an invalid set would presumably be completely unconstrained. Paraconsistent systems often have De Morgan negations. Philosophical debates about the acceptability of such logical systems often turn on the surprising cost of giving up explosion. Consider the following: If both P and $\neg P$ are true, we may choose an arbitrary Q and infer $(P \text{ or } Q)$ from P and then by so-called 'disjunctive syllogism' infer Q from $(P \text{ or } Q)$ and $\neg P$ – so we seem to have shown that explosion is a correct derived rule of inference. To block this argument, it seems we must: change our rule of 'or introduction'; hold that the result of stringing together deductively valid inferences is not always valid; or declare that disjunctive syllogism is not valid, despite appearances to the contrary. Many philosophers regard any of these as a higher price to pay than accepting the counterintuitive explosion rule.

Consider next the 'paradoxes of vagueness.' For concreteness, let $P(n)$ stand for 'there are more than n seconds in my childhood.' It seems we have good reason for accepting (i) $P(0)$ is true; (ii) for any n , if $P(n)$ is true then so too is $P(n + 1)$ (since one certainly does not change from a child to a nonchild from one second to the next); and (iii) for a sufficiently large m , $\neg P(m)$. However, $P(m)$ follows from (i) and (ii). In classical logic, rejecting (ii) implies that there is a number n such that one is a child for n seconds, but 1 second later one is not. However, in many logics this does not follow. In particular, many logics that reject the law of excluded middle avoid this conclusion. Indeed, the phenomenon of vagueness is thought by some to pose a more direct challenge to classical negation. The minimal logic condition applied to predicates instead of propositions means that $\neg P(x)$ picks out the property whose extension is as large as possible while remaining disjoint from the extension of $P(x)$. However, if $P(x)$ is vague, why should we suppose that all relevant x fall either in $P(x)$ or in $\neg P(x)$? To suppose there is always such a property seems to be assuming that every property has sharp

boundaries, which seems to amount to saying that there are no vague properties.

Finally, consider the ‘knowability paradox’: in classical logic, given some seemingly innocuous presuppositions about the nature of necessity and of knowledge, it follows from

(AR) all truths are *knowable*

that

(AK) *all truths are known.*

(Here is one set of assumptions suffices: knowledge distributes over conjunction; what is known is true; what is proved to be a theorem is thereby proved to be necessarily true; and if (necessarily $\neg P$) then \neg (possibly P).) Many philosophers are inclined to accept (AR), at least for certain domains of discourse, but almost none are tempted by (AK). However, the argument that (AR) implies (AK) depends essentially on double negation elimination. Hence, one can block the argument if negation is not De Morgan (e.g., if it is intuitionistic). Of course, to argue for this requires, if this solution is not to be merely *ad hoc*, giving independent reasons for rejecting classical negation – one could, after all, have rejected one of the plausible assumptions about necessity or knowledge instead, if blocking the paradox were alone sufficient to motivate such reformation of philosophical presuppositions.

More Than One Negation?

Some authors argue that it is a mistake to think that the same operation is involved in forming the negation of sentences and properties, something we have assumed without question. For instance, arguably the logical behavior of ‘ x is not- P ’ differs from that of ‘it is not the case that x is P ’; for example, x will be not-white only if x is definitely not white (i.e., is not a boundary case of whiteness), whereas if x is a boundary case, then it is not the case that x is white, but if the same operator is at work in both claims they should be equivalent.

Nonclassical languages sometimes suffer from a lack of expressive power if there is only one negation, in the sense that that negation leaves us unable to express what we seem able to express in natural language. For instance, $\neg P$, using intuitionistic negation, says that P is, in some suitable sense, impossible. (In both minimal and intuitionistic logic, $\neg P$ is often defined as ‘if P , then absurdity results.’ To see why this makes sense, look again at the characterization of minimal negation in the first section and note that adding explosion merely makes the consequences of absurdity particularly dire.) One loses the link to impossibility in De Morgan (and so classical) negations. For instance, with De Morgan negation

one can infer from $\neg(P \text{ and } Q)$ that $(\neg P \text{ or } \neg Q)$, but it certainly does not follow from the impossibility of P and Q being jointly satisfied that one of P and Q must be impossible. This matters because although one cannot intuitionistically derive (AK) from (AR), one can derive, for any P ,

(*) $\neg(P \text{ and } \neg(\text{It is known by someone at some time that } P))$

which is okay because this means only that it is impossible for P to be true and at the same time it be impossible for anyone to know it, which should follow from AR. However, if intuitionistic negation is the only one available it is difficult to see how one might express the claim that ‘some claims are true but never known’ since, as we have seen, (*) says something quite different. The obvious response is to argue that some other negation, compatible with but distinct from intuitionistic negation, is involved in expressing it. (Note that this other negation must be nonclassical, for if P has both a classical and intuitionistic negation, they are the same proposition, viz. the weakest proposition incompatible with P , so classical and intuitionistic negation cannot exist as distinct negation operators for the same class of sentences.) Similarly, if the only negation is the dialectic negation, how can we express things like ‘ P is true, and is not also false’?

Negation and Denial

Why not say, “The problem with (L) is that it *does not express a proposition*, and so *fails to have a truth value*”? Since it fails to have a truth value, so too does its negation – (L) and its negation fall into a *truth value gap*.” One reason is that this seems not to work for the so-called ‘strengthened liar’ (SL):

(SL) SL is not true.

For if (SL) is neither true nor false, then it is not true, and so should be true.

Notice that in our discussion of (L) we suggested that if P falls into a truth value gap, so too does $\neg P$, but in discussing (SL) we assumed that if P falls into a gap, not- P is true. If what we have said in both cases were correct, ‘not’ in the (SL) case is expressing some different notion of negation than is expressed by the negation sign in the (L) case, and we seem to be stuck with an ambiguity in the meaning of ‘not.’ It has been suggested, though, that ‘not’ is pragmatically, rather than semantically, ambiguous: It is sometimes used to form negations, and at other times it is used to deny a claim. When we say that (SL) is not true, we are denying (SL) without thereby asserting its negation.

However, we only fall back into paradox if we assert the negation of (SL). What makes this proposal philosophically contentious is that the prevailing view, going back at least to Frege, is that denial is not a separate speech act but is equivalent to the assertion of the negation of the claim in question.

Negation: Semantic Aspects

Classical and Nonclassical Negation

In logic, negation is an operation that applies to a sentence (or more generally a formula), thus yielding a new sentence. The sentence thus obtained is called the negation (or in some authors the denial) of the sentence negated. The negation sign is a logical operator, which is written in front of the relevant formula. The negation of a sentence φ is – depending on the notation convention adopted – written as $\neg\varphi$, $\sim\varphi$, $-\varphi$, $\bar{\varphi}$ or $N\varphi$. In Frege (1879), we find a small vertical stroke attached to the lower side of the content stroke. In his notation, the judgment that φ is not the case thus comes out as $\vdash\neg\varphi$.

In a classical two-valued logic (which allows exactly two truth values and moreover takes for granted that every sentence has a truth value), there is only one possible semantic definition of negation: the negation operator is a function that maps truth to falsity and falsity to truth. We may, however, deviate from classical semantics in various ways. One way is to question the assumption that every sentence has a truth value, another way is to allow for more than two truth values. This comes down to rejecting the principle of bivalence. The first strategy gives rise to so-called partial logics, the second to multivalent logics. A partial logic thus allows a sentence to have no value and it is common to refer to this third possibility as a truth value gap. In multivalent logics, we may define several negation operators; what their truth tables look like will depend on the intended interpretation of the nonclassical values. In a three-valued logic, a sentence that is not true may either be false or have the third truth value. In this view, falsity is a subcategory of what is not true. An alternative

account takes the third value as a special way of being not false. Finally, we may see the third value as independent of both truth and falsity. We thus may interpret the third value as a special way in which a sentence may go wrong and different interpretations will generally give rise to different truth tables.

Nonclassical accounts of negation go back to Aristotle. Aristotle argued (in his famous 'sea battle' argument) that if the sentence *There will be a sea battle tomorrow* were now either true or false, we would be committed to fatalism. Lukasiewicz concluded that such contingent future tense sentences are neither true nor false and consequently rejected bivalence. He introduced a third truth value to be interpreted as indeterminate or contingent, which naturally yields a truth table that maps truth to falsity, falsity to truth, and the third value to the third value. The Russian logician Bochvar gave another motivation for three-valued logics, arguing that it allows us to avoid logical paradoxes. Other writers have given various linguistic arguments for such deviations from classical logic. Three cases that received quite a bit of attention in the linguistic literature are category mistakes, vagueness, and presupposition failure.

Examples of category mistakes are Carnap's *Caesar is a prime number* or Chomsky's *Colorless green ideas sleep furiously*. Such sentences do not ascribe properties to things they do not have (which would result in falsity), but properties they cannot possibly have, thus yielding absurdity. And, since this holds for both the unnegated sentence and its negation, it gives a truth table that maps the third value (interpreted as nonsensical) on itself. The problem is closely related to the problem of presupposition failure (see below).

Vague predicates comprise predicates such as *small*, *beautiful*, *long*, etc., that is predicates that apply to a thing or set of things to a certain extent. In some cases, it is simply unclear whether a predicate

applies to an object. An example is Austin's *France is hexagonal*. Vague terms admit borderline cases, cases in which it cannot be uniquely determined whether a concept falls under the term or not. Three-valued logics are not of much help in solving the problem, since they replace the classic dichotomy between true and false with a strict trichotomy between true, false, and indeterminate, which yields results that are equally counterintuitive as those that result from a bivalent approach.

The most popular accounts are the so-called fuzzy logics introduced in the mid 1960s (Zadeh, 1965) and the method of supervaluations (Van Fraassen, 1966). Fuzzy logics accept an infinite number of truth values (a real number in the interval $[0, 1]$). The idea is that the closer the value is to 1 the 'truer' the sentence is. The value of a negated sentence is taken to be 1 minus the value of the unnegated sentence. Assuming that vague sentences get their value somewhere in the middle of the interval, it follows that if a sentence is maximally vague, so is its negation. The same holds for conjunctions and disjunctions of vague sentences. Fuzzy logics have been objected to on a number of counts. Most importantly, people have objected to the artificiality of assigning precise numerical values to the degree to which an object is small or beautiful. An alternative account is found in the method of supervaluations. Supervaluations – which were originally developed to account for presupposition failure – differ from multivalent logics in that they accept only two truth values but allow truth-value gaps. Just as in fuzzy logics, the negation of a vague sentence will come out as vague; but in contrast to fuzzy logics, formulas that are classically valid (or contradictory) will always come out as true or false no matter what the values are of their atomic components. A comparison between the approaches and a linguistic application is found in Kamp (1975).

Some of the best-known deviations from classical logic originate from presupposition theory. For Frege (1892) and Strawson (1952), presuppositions act as preconditions a sentence should satisfy in order to be true. Strawson and many other authors took preservation under negation as the defining characteristic. Thus (1b) seems to suggest as strongly as its unnegated counterpart (1a) that (1c) is true.

- (1a) The king of France is bald.
- (1b) The king of France is not bald.
- (1c) France has a king.

This phenomenon is general and seems to hold for all other lexical items that are said to induce presuppositions:

- (2a) John quit smoking.
- (2b) John didn't quit smoking.
- (2c) John used to smoke.

Inspired by Strawson the so-called neo-Strawsonians turned preservation under negation into a definition of semantic presupposition:

- (3) A sentence φ presupposes ψ just in case
 - (i) φ entails ψ ; and
 - (ii) $\neg \varphi$ entails ψ .

If we assume that negation maps truth to falsity and vice versa and, if we also adopt the standard definition of semantic entailment (φ entails ψ iff for any model M if $[[\varphi]]^M = 1$ then $[[\psi]]^M = 1$), (3) is equivalent to

- (4) φ presupposes ψ just in case
 - (i) in any model in which $[[\varphi]]^M = 1$ it holds that $[[\psi]]^M = 1$; and
 - (ii) in any model in which $[[\varphi]]^M = 0$ it holds that $[[\psi]]^M = 0$.

The latter simply comes down to the idea that if a sentence φ presupposes a sentence ψ , φ cannot have one of the classical values true or false, unless ψ is true. In a classical two-valued logic, this would predict that sentences can only presuppose tautologies. This forces the theorist to either allow for truth-value gaps or alternatively to introduce a third value to account for presupposition failure. If we allow truth-value gaps, compositionality predicts that if the unnegated sentence has no value, its negated counterpart will not have a value either. In a three-valued logic, this is captured by adopting the following truth table for negation (* indicates the third value):

(5)

φ	$\neg \varphi$
1	0
0	1
*	*

In conjunction with definition (3), this correctly predicts that presuppositions are preserved under negation.

Russell pointed out that (1b) has a second reading according to which this sentence is true simply because there is no king of France. In his analysis, the difference between the two readings is cashed out in terms of scope. In addition to the 'standard' interpretation, which is obtained by giving negation narrow scope and thus yields the formula (6a), we obtain the second reading by giving the negation scope over the full formula as in (6b):

- (6a) $\exists x \forall y [[KF(x) \leftrightarrow x = y] \wedge \neg \text{Bald}(y)]$
- (6b) $\neg \exists x \forall y [[KF(x) \leftrightarrow x = y] \wedge \text{Bald}(y)]$

This retains classical two-valued negation and eliminates presuppositions. It also illustrates the idea, found in Frege, that negation can always be represented as the standard operator suitably placed in the logical representation.

Russell's theory eliminates presuppositions. However, the difference between a presupposition preserving and presupposition canceling interpretation can also be obtained in a three-valued logic by defining a second negation operator $\neg \varphi$ that maps the third value onto truth:

(7)

φ	$\neg \varphi$
1	0
0	1
*	1

We perceive two kinds on nontruth. Nontruth as plain falsity and nontruth as a result of presupposition failure. The operator given in (5) is known as the weak Kleene-negation or the internal Bochvar connective; the operator defined in (7) is the same as the external Bochvar negation (also called the denial operator).

Negation and Polarity

Natural language contains a class of expressions whose distribution is limited to contexts that feel negative. Such items are called negative polarity items (NPIs). NPIs come in various types and syntactic categories: quantifiers and quantifier phrases (*any*, *any book*), verbs (*bother to*), factives (*mind that*, *matter that*), adverbs (*ever*, *yet*), prepositions (*until*), modals (*need*), idioms (*give a damn*, *lift a finger*), and many more. Thus the a sentences below, where we find the NPIs *any* and *ever* in the scope of a negative expression, are fine, but the b sentences are unacceptable.

- (8a) Mary didn't find any coin.
 (8b) *Mary found any coin.
 (9a) No one ever squared the circle.
 (9b) *Somebody ever squared the circle.

In addition to NPIs, we find a class of positive polarity items (PPIs). Positive polarity items typically occur in non-negative contexts. Just like NPIs, they belong to various syntactic categories. Examples of PPIs are quantifiers like *each* and *some*, factives like *be delighted that*, adverbs like *already*, and a rich variety of other expressions. The following examples show that PPIs shun negation:

- (10a) Harry is already serving breakfast.
 (10b) *Harry is not already serving breakfast
 (11a) Everybody inspected each package.
 (11b) *Nobody inspected each package.

Contexts that license NPIs however, need not contain overt negative elements. Thus negative polarity elements may be allowed in, for example, conditionals and *before*-clauses.

- (12a) If you find any clue, you should report it to the police.
 (12b) Mary left before John* already/even arrived.

In addition, some types of contexts only allow certain subclasses of polarity items. The central problem is thus to give a general characterization to the classes of contexts that license NPIs and PPIs and to relate different subclasses of polarity elements to the contexts that license them. On the question of why natural language contains such items and in view of what semantic properties makes them they behave as they do, there is no agreement whatsoever. Though most authors assume that there is a general mechanism that governs all such items, they also assume that positive or negative polarity is at least in part a conventional feature that is given in the lexicon.

Klima (1964) called contexts that license NPIs, affective contexts. Affective contexts in Klima's sense are contexts that are either explicitly negative or contain an underlying negative element NEG. Related views are put forward by Baker (1970) and Linebarger (1980), who claim that NPIs are licensed by negative contexts but the negative element need not surface. Baker requires that the licensing context be either negative or entail a negative sentence. Linebarger states that a NPI may be licensed by an overt negative element or a negative implicature. Ladusaw (1979) was the first to propose a semantic characterization of negative context as a NPI licenser. According to Ladusaw, an expression acts as a trigger for NPIs if it denotes a downward entailing function. The central notion is downward entailment or downward monotonicity. The definition runs as follows:

A function is downward entailing (monotone decreasing, downward monotonic) iff for all X and Y: if $X \subseteq Y$, then $f(Y) \subseteq f(X)$.

We can test for downward monotonicity by checking whether a context validates inferences from sets to subsets. Given that $\|chickpeas\| \subseteq \|peas\|$, the inference from (13a) to (13b) holds:

- (13a) Mary doesn't eat peas.
 (13b) Mary doesn't eat chickpeas.

And this predicts that (14a), where we find the NPI *any* in a downward entailing environment, is fine, though (14b) is unacceptable.

- (14a) Mary doesn't eat any peas.
 (14b) *Mary does eat any peas.

The converse property is upward entailment or upward monotonicity.

A function f is upward entailing (upward monotonic) iff for all X and Y : if $X \subseteq Y$, then $f(X) \subseteq f(Y)$.

The inference from *Some Texans eat chickpeas* to *Some Texans eat peas* is valid, which shows that *Some Texans* is upward entailing.

Most authors agree that Ladusaw's generalization is basically right when taken as a necessary condition (e.g., Van der Wouden). In order to license an NPI, the context should have the property of downward monotonicity. Zwarts (1986), Hoeksema (1983), and van der Wouden (1997) show that the issue is more complicated, however. Not all NPIs are licensed in all downward monotonic contexts. As a consequence, they distinguish between weak and strong NPIs (Zwarts) or between weak, medium, and strong ones (Van der Wouden). Weak NPIs conform to Ladusaw's generalization, NPIs of medium strength and strong ones require contexts that satisfy additional algebraic properties. The picture that arises from this work is that polarity licensing of both NPIs and PPIs is not a homogeneous phenomenon.

There is an additional complication. According to the characterization given above, putting a PPI in a negative context yields ungrammaticality. However, such constructions often allow for a special interpretation that suggests that the corresponding non-negative sentence has been uttered before. Seuren (1985) calls this the 'echo' effect and takes it as an argument for the existence of a special presupposition-canceling negation operator. For Horn (1985, 1989), it is a diagnostic for a special use of negation he calls metalinguistic. Thus (15) is acceptable as a reaction to the utterance of *Mary is still in Paris*.

(15) Mary is NOT still in Paris. She never intended to be there and went to London instead.

It is implausible, though, that this phenomenon has anything to do with the formal properties of negation or negative context. We observe the same effect when NPIs are put in uncontroversially positive contexts.

(16) It DOES matter that my bunny is ill.

We return to the phenomenon of polarity reversal at the end of the last section.

Negation Versus Denial

The negation of a sentence is sometimes called its denial. It is, however, important to strictly separate the concepts of denial and negation. The concept of denial belongs to speech act theory. In this respect,

denials are on a par with assertions. And, in contrast to negation, denials – just like assertions – should not be characterized in terms of truth and falsity but in functional terms. The primary function of assertions is to introduce new information, that is information that is not already taken for granted by the participants in a discourse. Denials differ in this respect. Their essential function is to object to information that has already been introduced before or is in some sense taken for granted. In doing so, a denial will have the effect of removing information from the discourse record. Despite being overtly negative, (17a) and (17b) will, if processed as the first sentence of a discourse, not be interpreted as denials but as assertions of negative sentences.

(17a) Mary is unhappy/not happy.

(17b) It does not matter that Mary read your letters.

Note, moreover, that a denial need not contain a negative morpheme. If uttered as a reaction to (17a) or (17b), B-b and B-c below will not be interpreted as assertions but as denials of the utterances they object to. The utterance by means of which the denial is performed may thus be of a negative or positive form. This shows that the concept of denial is logically independent of the concept of negation.

The difference in status of the concepts of denial and negation gave rise to a view according to which denials can be semantically characterized in terms of assertion and negation. Following Frege–Austin, Searle, and Dummett claimed that denials can be semantically analyzed as assertions of negative sentences. Further pragmatic effects that distinguish denials from assertoric utterances must be accounted for independently. Frege (1918: 149; Geach 1997: 40) – states: "People speak of affirmative and negative judgments; even Kant does so [...] For logic at any rate such a distinction is wholly unnecessary; its grounds must be sought outside logic." A linguist like Givón (1978) implicitly adopts the view that negation in language should be analyzed as a logical sign, which operates on sentences, but points out that denials have, in addition to their logical aspect, a pragmatic function that should be treated independently. Thus, though denials should logically be treated as negations of positive sentences, they constitute a different speech act from assertions. "While the latter are used to convey new information on the presumption of ignorance of the hearer, negatives are used to correct misguided belief on the assumption of the hearer's error." (Givón, 1978).

However, Frege also points out that it is not easy to make sense of the interpretation of denials as negative statements. "It is by no means easy to state what is a

negative judgment (thought). Consider the sentences ‘Christ is immortal’, ‘Christ lives for ever’, ‘Christ is not immortal’, ‘Christ does not live for ever’. Now which of the thoughts here is affirmative, which negative?ⁿ (Frege, 1918: 150; Geach 1977: 41). The central problem is that a treatment of the negation sign as a sign of denial forces us to introduce a further operator to account for negatory or denial force, in addition to the negation operator. Clearly, no operator that would go or fuse with Frege’s assertion sign can be given a sensible interpretation in an embedded environment. Though an interpretation could be given to such an operator for simple sentences in an unembedded environment, it precludes the possibility of using this very same sentence as the antecedent of a conditional sentence. In this context, the sentence cannot have denial of negatory force. Fregean force always goes with full sentences and does not contribute to the proposition expressed. Thus in embedded environments, negation can only be interpreted as an ordinary functional expression, reversing the truth value of the proposition expressed. However, the introduction of some kind of denial operator having the same role as assertion would force us to recognize two ways of judging and accordingly two negative operators of a different status, one as some kind of speech act device, the other as a semantic operator reversing the truth value of the proposition expressed. Consequently, we should separate force from content, thus ending up with a theory that is preferable for being both conceptually and formally simpler.

Metalinguistic Negation

Horn (1985, 1989) drew attention to the fact that an utterance may not just be rejected in view of falsity of the propositional content, but that denials may instead apply to a variety of information, comprising presuppositions, various types of implicatures and connotations related to style and register. He points out that denials can be used to reject an utterance of a previous speaker for whatever reason. And equating the notions of denial and negation, he made a distinction between the well-known truth-functional operator and a non-truth-functional metalinguistic device. On this view, standard truth-functional negation is found in negative assertions and propositional denials. His metalinguistic device applies to presuppositional inferences, implicatures, and connotations of style and register. He labeled this device ‘metalinguistic negation’ and characterized it as follows: “I am claiming [...] for negation [...] a use distinction: it can be a descriptive truth-functional operator, taking

a proposition p into a proposition $\neg p$, or a metalinguistic operator which can be glossed ‘I object to u ’, where u is crucially a linguistic utterance rather than an abstract proposition” (Horn, 1985: 136). The relevant examples can be classified in the following categories:

- A Assertions of negative sentences:
 - (A-a) Mary is unhappy.
 - (A-b) Mary is not happy.
 - (A-c) It does not matter that Mary read your letters.
- B Propositional denials:
 - (B-a) Mary is NOT happy (as a reaction to the utterance of ‘Mary is happy’).
 - (B-b) Mary is happy (as a reaction to the utterance of A-a or A-b).
 - (B-c) It DOES matter that Mary read my letters.
- C Presuppositional denials:
 - (C-a) The king of France is NOT bald – France does not have a king.
 - (C-b) Virginia CANNOT know that the earth is flat.
 - (C-c) John DIDN’T stop smoking – he never smoked.
- D Implicature denials:
 - (D-a) It is not POSSIBLE, it is NECESSARY that the church is right.
 - (D-b) That haggis is not GOOD, it is EXCELLENT.
 - (D-c) That was not a LADY I kissed last night – it was my WIFE.
- E A variety of connotations (conventional implicature, style, register)
 - (E-a) That is not a STEED – it’s a HORSE.
 - (E-b) Grandma didn’t KICK THE BUCKET – she passed away.
 - (E-c) He didn’t call the police, he called the POLICE.

Abstracting from their discourse function and focusing on truth conditional content, we may first note that Frege’s strategy of analyzing the denial B-a as an assertion of a positive sentence works as far as truth conditional content goes. Assuming double negation in their underlying form, B-b and B-c can also be analyzed in the Fregean way. The presuppositional denials under C have historically either been handled by means of some nonstandard logic (thus postulating an ambiguity in the negation operator), or by an appeal to the Russellian notion of scope (see the first section above). More recent accounts that are formulated in a dynamic framework achieve a similar effect by invoking the notion of local accommodation.

Though such theories take it that presuppositions normally escape from the scope of negation and other embedding operators, they introduce a special mechanism that forces presuppositional information – under specified conditions (e.g., threatening inconsistency) – to remain *in situ*, i.e., the place where they were triggered, and thus keep them within the scope of the embedding operator (Heim, 1983; Van der Sandt, 1992). The examples under D and E are problematic for any purely logical account. Their standard translations amount to plain contradiction, which led authors to call for some non-truth-functional analysis or else a nonliteral reinterpretation in view of a violation of Gricean maxims.

Horn treats categories C–E as metalinguistic uses of negation. The following diagnostics act as a kind of litmus test:

- Metalinguistic negation requires wide scope, thereby blocking lexical incorporation.
- Such sentences exhibit a rising intonation contour (fall-rise) pending further clarification, thereby stressing the offensive item or else triggering contrastive stress on the negative morpheme.
- Metalinguistic negation reverses the polarity of the sentence.

Example (18) illustrates the first diagnostic. In contrast to example D-a, it amounts to a straightforward contradiction:

- (18) It is impossible, it is necessary that the church is right.

Note, moreover, that the same holds for example D-a if we destress the offensive item *possible*. Sentences (15) and (16) show that – contrary to received wisdom – negative denials accept PPIs, while positive denials allow NPIs.

Van der Sandt (1991, 2003) stressed that in view of their function, denials should be interpreted in context. They are not incremental in the sense assertions are, nor can they naturally occur in isolation. They take up or ‘echo’ a previous utterance; and since utterances convey information of various kinds (comprising presuppositions, implicatures, and further connotations), the interpretation of a denial may be sensitive to all the information that is invoked by the utterance they object to. Just as a speaker, when uttering any of the B sentences, objects to the truth-conditional content of a previously uttered sentence, he objects in the C cases to the presuppositions carried by a previous utterance, in the D cases to implicatures invoked, and in the E cases to offensive connotations of style and register a previous speaker

may have conveyed with a corresponding non-negative utterance. Consider (19b), which is typically a reaction to (19a)

- (19a) It is possible that the church is right.
 (19b) It is not POSSIBLE, it is necessary that the church is right.

The utterance of (19a) invokes the implicature that it is not necessary that the church is right. By denying this utterance by means of (19b), the second speaker does not just react to the propositional content but to all the information conveyed by (19a). This information comprises the (scalar) implicature that it is not necessary that the church is right. Thus, if we take the negation in (19b) to apply to the full informative content of the first utterance, this yields an interpretation that can be paraphrased as (20):

- (20) $\neg(\Diamond \text{the_church_is_right} \wedge$
 $\neg \Box \text{the_church_is_right}) \wedge$
 $\Box \text{the_church_is_right}$

This simply conveys that it is necessary that the church is right and rejects all information conveyed by the previous utterance. The formal account is implemented in a nonincremental theory of discourse processing.

While Horn subsumes only presuppositional denials, implicature denials and the style and register cases under his notion of metalinguistic negation, Van der Sandt takes the phenomenon to be fully independent of the notion of negation and proposes an explanation of both the Horn cases and propositional denials based on the discourse properties of denial. Geurts (1998) objects to both views. According to him, denial or metalinguistic negation is not a homogeneous phenomenon. Instead he claims that a different semantic mechanism is operative in each of the cases B–E. His account divorces metalinguistic negations from the discourse characteristics of denial. Propositional denials are simply assertions of negative sentences. Presuppositional denials are handled by the mechanism of local accommodation. For the last two categories, Geurts assumes that the negative morpheme operates on a different level. For implicature denials, he invokes the notion of semantic polysemy. Crucially, he maintains that a scalar like *possible* may either have an *at least* or an exhaustive sense (i.e., *possible and not necessary*). Example (19a) selects the *at least* interpretation and here the exhaustive interpretation comes about by way of conversational implicature. In the denial (19b), the exhaustive sense is selected immediately. Only the style and register and pronunciation cases are metalinguistic in that they make reference to linguistic objects. Example

E-b typically corrects the pronunciation of *police*. In this context, the phrase POLice corrects pronunciation, and here this phrase may be constructed as ‘the body whose name is pronounced “police”.’

Returning to the second section of this article, I conclude with a remark on polarity reversal. On the account that strictly distinguishes between the use of a (negative) sentence to convey new information and its use as a denial, polarity reversal falls out as a consequence of the discourse function of denial.

Consider first the unmarked (21a) and (21b):

(21a) It does not matter that Mary has read my letters.

(21b) Harry did not pick any of the flowers.

A denial interpretation of either of these sentences would require that the corresponding non-negative sentence has been uttered just before (or is at least ‘in the air’). Note that their non-negated counterparts would contain a negative polarity element in a non-negative context and thus be ungrammatical. This forces the regular assertoric interpretation. But (16), which does contain an NPI in a non-negative context, can very well be used to echo a negative and thus grammatical utterance. An analogous explanation can be given for negative sentences containing PPIs. Since affirmative sentences containing PPIs require a non-negative context, their negated counterparts cannot be interpreted as isolated assertions. But they can very well be interpreted as the denial of a previous utterance, which being positive, is fully grammatical. Sentence (15) illustrates this.

Nominalism

G Klima, Fordham University, Bronx, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Nominalism is usually characterized in contrast to other two major theoretical alternatives concerning the ontological status of universals. According to this characterization, the nominalist position holds that universals are mere words (e.g., the word ‘round’); in contrast, the conceptualist position would identify universals with concepts (e.g., the concept expressed both by the English word ‘round’ and by the Latin word ‘rotundus’), and the realist position would claim universals to be universal things (e.g., the nonmental, nonphysical, abstract Form of Roundness itself).

Both historically and theoretically, there are a number of problems with this simple, indeed, simplistic conception. First, by these standards, no premodern author would qualify as a nominalist since all these authors held that our universal terms owe their universality to the universal concepts they express (thus, on this account all these authors would have to be classified as conceptualists), and no medieval author would count as a realist because they all denied the real existence of Platonic ‘abstract entities’ (although most medieval authors did posit universals both *in re*, as trope-like individualized forms such as the individual roundness of *this* billiard ball as opposed to the numerically distinct roundness of another one, and *ante rem*, as Divine Ideas, identical with God, who is not an ‘abstract entity’) (Klima, 2001). Accordingly, this conception leaves in obscurity the genuine theoretical differences of medieval nominalists and realists, who first distinguished themselves under these designations. However, as we shall see, clarifying these genuine theoretical differences, we can have a deeper understanding not only of what a genuinely nominalist position was in the late Middle Ages but also what in general a genuinely nominalist position has to consist in, as well as the important conceptual connections such a position has to such broader issues as ontological commitment, abstraction, induction, essentialism, and the possibility of valid scientific generalizations.

Extreme Realism: Plato’s Ideal Exemplars

The problem of universals originated with Plato’s answer to the question of how universal knowledge (e.g., our knowledge of geometrical theorems) of a potential infinity of individuals is possible. Plato’s answer in terms of his theory of Forms involves the idea of regarding individuals of the same kind as

copies of an original exemplar or archetype and assuming that our understanding has some direct access to this exemplar. Clearly, if I can read today’s news on the printer’s printing plates, then I do not have to buy the copies at the newsstands to get my news. Likewise, knowing that the form of all triangles, after which all triangles are modeled, has three angles equal to two right angles, I know that all triangles have the same property. Thus, Plato’s answer is obviously a good answer to the question of the possibility of universal knowledge. However, this answer raises more problems than it solves. If the exemplar is not one of the copies, yet it has to be like the copies (given that the copies all have to be like it), then what sort of entity is it? In fact, this is precisely the basis of the most famous argument against Plato’s theory, the Third Man (Wedberg, 1978). For if the exemplar has to be of the same sort as its copies, it can be grouped together with its copies into the same kind. However, if for a group of individuals of the same kind there always has to be a common exemplar, and nothing can be its own exemplar, as Plato’s theory claims, then there has to be another exemplar for the exemplar and its copies taken together. Since this reasoning can be repeated indefinitely, we have to conclude that for a given set of copies there would have to be an infinity of exemplars, contrary to the theory’s explicit claim that there can only be one such exemplar. Therefore, since the theory as stated entails inconsistent claims, it cannot be true in this form.

Moderate Realism or Conceptualism: Aristotle’s Universals

Prompted by such and similar inconsistencies, Aristotle famously rejected Plato’s Forms and provided a radically different sort of answer to Plato’s original question concerning the possibility of universal knowledge. Plato’s idea was that this sort of knowledge is possible because of the human soul’s prenatal access to the Forms serving as the common exemplars of all sorts of particulars the soul comes to experience in this life and the soul’s ability to recollect these Forms and their properties prompted by these experiences. In contrast, Aristotle’s idea was that we can have this sort of knowledge from experience in this life. To be sure, the finite number of experiences we can have in this life with individuals of the same sort can never justify universal knowledge claims that cover a potential infinity of such individuals. However, if our cognitive faculties enable us to recognize a common pattern that equally

characterizes any possible individual of the same sort, then even this finite number of experiences may enable us to make valid generalizations covering all possible individuals of the same sort. Using the previous analogy, in this case I do not have access to the printer's plates (if there is any such thing at all, which need not be the case if copies can 'self-reproduce,' as in photocopying); I can only collate a number of variously smudged, incomplete newspapers, from which, nevertheless, I am able to extract their common content so that I will know the news any other copy of the same issue may carry even before actually checking it. This is the idea Aristotle worked out in his theories of abstraction and induction.

The Moderate Realism/Conceptualism of Medieval Aristotelians

According to Aristotle and his medieval interpreters, human understanding is characterized by two intellectual powers or faculties, namely the active intellect (*nous poietikos*, *intellectus agens*) and the receptive intellect (*nous pathetikos*, *intellectus possibilis*). Due to the obscurity of Aristotle's formulations, in the Middle Ages there was much debate about the makeup of these faculties, namely whether they are material or immaterial, and whether they existed as individualized powers of individual human souls or, rather, as separate substances connected to individual human souls to carry out their intellectual operations (pretty much as mainframe computers are connected to their terminals). However, regardless of these differences, there was quite general agreement concerning the function of these intellectual powers (whatever they are in themselves) and how they can produce universal knowledge without having to 'look up to' or 'recollect' Platonic Forms. The active intellect has the function of producing simple, universal concepts (i.e., universal representations of individuals) from their singular representations provided by the senses. The receptive intellect, on the other hand, receives these universal representations for further processing, combining them into more complex concepts and judgments by means of complexive concepts, the so-called syncategorematic concepts ('syncategoremata'), and using these judgments in reasoning.

Abstraction, Induction, and Essentialism

In the process of abstraction, the active intellect forms a common concept by considering the multitude of experiences of particulars of the same kind, disregarding what is peculiar to each while focusing on what is common to all. The common concept retained

in the receptive intellect is a mental representation that represents the individuals it is abstracted from only with respect to what commonly characterizes them all. Accordingly, the same mental representation will naturally represent in the same respect not only those individuals that it is abstracted from but also other individuals of the same kind – that is, individuals that resemble the observed ones precisely in the same respect in which the abstracted concept represents the observed individuals. Therefore, if the receptive intellect forms a judgment with this concept in which the predicate belongs to the particulars that fall under this concept on account of falling under this concept, then it is able to produce a valid scientific generalization by induction – that is, by reasoning in the following way: This observed S was P, and that observed S was P, and so on for all observed S's; therefore, in general, every S is P. Obviously, this inference is valid (not formally, but materially) only if an S is essentially and not merely coincidentally P – that is, if an S is P on account of being an S so that any S is necessarily P, as long as it is an S (and if it is also essentially an S, then it is necessarily an S, and hence also a P, as long as it exists). This is precisely why this inference requires the multitude of experiences, namely to ensure that the observed S's have been P not by mere coincidence but precisely on account of being S's. However, if this inference is valid, then it obviously provides a good answer to Plato's original question (concerning the possibility of universal knowledge) without resorting to Plato's universal Forms.

The Ontological Commitments of Moderate Realism

However, the previous conception may still involve an enormous amount of ontological commitment; admittedly, not to Platonic universal Forms but to individuals of a rather strange sort, the individualized forms of individual substances. If all our common terms are applicable to individual things on account of our common concepts, and we gain these concepts by abstraction from the individualized forms or properties that sort individuals into various kinds, then apparently there are as many individualized forms in an individual substance as there are true common predicates of it. (Yet, this conception need not make individual substances into mere congeries of individualized forms, in the vein of modern trope theories. On this conception, individual substances are the primary units of reality that account for the individuation of individualized forms, and not the other way around (cf. Campbell, 1997; Daily, 1997).) In this moderate realist view, commonly endorsed

by medieval authors of the 13th century (e.g., Thomas Aquinas), the world is a world of individuals without ‘universal entities,’ but it is populated by all sorts of nonsubstantial particulars, serving as the individualized *significata* of our common terms. The universals of this world, then, are the common terms of our language as well as the concepts they express, and the individualized forms as-conceived-in-a-universal-manner by means of these concepts (i.e., as-existing-in-the-mind as the direct objects of these concepts) (Klima, 1999). To be sure, these authors were able to reduce the ontological commitment of their theories by two fundamental semantic strategies: the distinction of several senses of ‘being’ and the identification of the semantic values of various terms.

On the first strategy, ontological commitment simply becomes ambiguous among different kinds of entities credited with different degrees of reality corresponding to different senses of ‘existence’ or ‘being’ (such as being in reality, *esse reale*, and being in the mind, *esse rationis*; cf. Klima, 1993) – a move generally rejected by nominalists.

On the second strategy, however, ontological commitment is reduced even within the same domain of entities. For instance, since two billiard balls A and B are similar in shape, the moderate realist view is apparently committed not only to the individualized roundness of A and the individualized roundness of B but also to the individualized similarity of A to B and to the individualized similarity of B to A. However, several moderate realist authors would argue that nothing prevents us from saying that the roundness of A is the same thing as the similarity of A to B, merely conceived differently, by means of a different concept (Henninger, 1989; Brower, 2001).

Late Medieval and Modern Nominalism

This strategy actually anticipates the more radical reductionist program of William Ockham and his 14th-century followers, such as John Buridan, Albert of Saxony, Marsilius of Inghen, and in general the late medieval nominalist tradition of the *via moderna*. These nominalist authors agreed with their moderate realist counterparts in positing a world consisting only of individuals and identifying universals with universal terms of written and spoken languages, which owe their universal mode of representation to universal concepts of the human mind, interpreted as singular mental acts representing their singular objects in a universal manner. However, they denied even the ‘diminished’ existence of universals as universal objects of these mental concepts admitted by moderate realists, and they reduced the number of

really distinct categories of singulars to two or three, admitting distinct entities only in the categories of substance, quality, and possibly quantity. (Ockham, for example, identified substance with quantity, whereas Buridan argued against their identification.)

To be sure, using their own eliminative strategy of identifying the semantic values of linguistic items in different linguistic categories, the moderate realists could in principle achieve the same degree of ontological parsimony. However, for them this was to be achieved separately, based on metaphysical considerations. Their semantics demanded positing as many different types of semantic values for their terms as there are different linguistic categories, although it was possible for them to decide on the basis of further metaphysical considerations about the identity or nonidentity of these semantic values. In contrast, the nominalists had the principles of ontological reduction (i.e., eliminating unwanted ontological commitment) ‘built into’ their semantic principles (Klima, 1999). The reductionist program of the nominalists was devised to show that it is possible to have a sufficiently ‘fine-grained’ semantics without a complex ontology by ‘moving’ the requisite distinctions from (a full-fledged or ‘diminished’) reality to the conceptual structures posited in the mind.

For example, in contrast to the moderate realist interpretation of similarity alluded to previously, in the nominalist approach there is no metaphysical question of whether the relation signified by the term ‘similar’ is identical with its foundation, for example, the roundness of ball A. The signification of ‘similar’ is not construed in the same way in the first place. Instead of assuming that in ‘A is similar to B’ this term signifies A’s similarity to B, an extramental entity that may or may not be distinct from the roundness of A, the nominalists would say that this term simply signifies A in relation to B, on account of the relative (connotative) concept whereby we conceive of A in relation to B. Therefore, even if we do have the obvious semantic difference between the absolute term ‘round’ and the relative term ‘similar,’ this semantic difference need not be accounted for in terms of a bloated ontology of distinct extralinguistic correlates of these terms because the relevant semantic distinctions can be made with reference to conceptual distinctions in the mind.

Following this nominalist strategy, once we have identified a basic ‘vocabulary’ of simple concepts that only commit us to entities in the ‘permitted’ ontological categories, any further apparent ontological commitments of our language can be eliminated by means of nominal definitions, which show how the semantic features of linguistic items carrying such apparent ontological commitment can be

accounted for in terms of an implicit conceptual structure that can be explicated by means of the basic vocabulary carrying commitment only to permitted entities. Indeed, this strategy of eliminating ontological commitment by means of nominal definitions explicating this implicit conceptual structure foreshadows the similar strategy of elimination by paraphrase characteristic of all modern nominalistic programs.

Thus, in this approach, and this is the gist of medieval nominalism in general, a sufficiently fine-grained semantics for natural language is achieved by mapping linguistic constructions onto sufficiently rich conceptual structures in a mental language (comparable in its role to the contemporary 'language of thought hypothesis'), which in turn can be mapped onto a parsimoniously construed reality without any loss of semantic distinctiveness.

Modern nominalistic programs, such as the program promulgated by Goodman and Quine (1947), apply the same basic strategy, but without the medievals' appeal to a mental language, by introducing the explicit ontological commitment of a primitive vocabulary and by eliminating any further apparent commitment (e.g., to such 'abstract entities' as numbers) by providing suitable paraphrases of relevant linguistic items (e.g., numerals) in terms of this primitive vocabulary. Indeed, in this program, Platonistic descriptions of language in terms of linguistic types are replaced by a nominalistic syntax treating of tokens, such as singular inscriptions. (In fact, medieval nominalists also formulated their logical theories in terms of token-phrases (Klima, 2004a).) The successful paraphrase then shows that there is no need to assume the existence of the putative entities apparently required by the semantic features of the phrases that appeared to carry commitment to them, so nominalists are entitled to get rid of them by one swoosh of Ockham's razor.

Nominalism, Antirealism, and Skepticism

Yet, despite customary charges and modern tendencies to the contrary, the 'reductionist' program and the corresponding strategy of medieval nominalism did not necessarily result in metaphysical anti-realism, conventionalism, or skepticism. Medieval nominalists typically regarded concepts as naturally representative of a world of individuals presorted into natural kinds and not sorted into these kinds by our concepts and/or linguistic conventions. Thus, they maintained an essentialist metaphysics, and so the scientific knowability of a mind-independent reality, yet without any ontological commitment to (whether

subsistent or inherent) universal essences distinct from their individuals. Whether they could consistently do so is a further issue, which bears direct relevance to contemporary considerations concerning ontological commitment and metaphysical essentialism. Plato's problem of the possibility of universal knowledge still remains a problem for nominalists: Once they have rejected the moderate realists' distinct individualized forms, which in the moderate realist conception are precisely the items in reality that serve as the foundation for the abstraction of our universal concepts, the nominalists still have to provide a plausible story about how universal concepts can be abstracted from observed singulars (and hence how they can apply even to previously unobserved singulars), unless they want to give up on the possibility of universal knowledge in the classical sense altogether (Klima, 2004b, 2005).

Nonmonotonic Inference

K Frankish, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

In most logical systems, inferences cannot be invalidated simply by the addition of new premises. If an inference can be drawn from a set of premises *S*, then it can also be drawn from any larger set incorporating *S*. The truth of the original premises guarantees the truth of the inferred conclusion, and the addition of extra premises cannot undermine it. This property is known as *monotonicity*. (The term is a mathematical one; a monotonic sequence is one whose terms increase but never decrease, or vice versa.) *Nonmonotonic* inference lacks this property. The conclusions drawn are provisional, and new information may lead to the withdrawal of a previous conclusion, even though none of the original premises is retracted.

Much of our everyday reasoning is nonmonotonic. We frequently jump to conclusions on the basis of partial information, relying on rough generalizations – that people usually mean what they say, that machines usually work as they are designed to, that objects usually stay where they are put, and so on. We treat these conclusions as provisional, however, and are prepared to retract them if we learn that the cases we are dealing with are atypical. To take an example that is ubiquitous in the literature, if we know that Tweety is a bird, then we may infer that Tweety flies, since we know that birds typically fly, but we shall withdraw this conclusion if we learn that Tweety is an atypical bird – a penguin, say.

An important feature of inferences like this is that they are sensitive to the absence of information as well as to its presence. Because we lack information that Tweety is atypical, we assume that he is not and proceed on that basis. (That, of course, is why the acquisition of new information can undermine the inference.) In standard logics, by contrast, inference is sensitive only to information that is explicitly represented, and we would need to add the premise that Tweety is not atypical in order to reach the conclusion

that he flies. This feature of nonmonotonic inference makes it highly useful. We do not have the time or mental capacity to collect, evaluate, and process all the potentially relevant information before deciding what to do or think. (Think of everything we would need to know in order to be sure that Tweety is not atypical – that he is not a penguin, not an ostrich, not a hatchling, not injured, not tethered to the ground, and so on.)

Because of its central role in commonsense reasoning, nonmonotonic inference has attracted much interest from researchers in artificial intelligence – in particular from those seeking to model human intelligence in computational terms. The challenge has been to *formalize* nonmonotonic inference – to describe it in terms of a precisely defined logical system that could then be used to develop computer programs that replicate everyday reasoning.

Nonmonotonic logic also has applications to more specific problems in artificial intelligence, among them the so-called *frame problem* (McCarthy and Hayes, 1969; see also **Frame Problem**). In order to plan how to reach its goals, an artificial agent will need to know what will and what will not change as a result of each action it might perform. But the things that will *not* change as a result of an action will be very numerous, and it would be impracticable to list them all in the system’s database. A more efficient solution would be for the system to reason nonmonotonically, using the rule of thumb that actions leave the world unchanged except in those respects in which they are known to alter it. Another application is in the area of database theory. Here it is often convenient to operate with the tacit assumption that a database contains all the relevant information and to treat as false any proposition that cannot be proved from it. This is known as the *closed world assumption* (Reiter, 1978). Again, this involves a nonmonotonic inference relation, since the addition of new data may permit the derivation of a proposition that was previously underivable and had thus been classified as false. Further areas of application include reasoning about

natural kinds, diagnostic reasoning, and natural language processing (Reiter, 1987; McCarthy, 1986).

Work on formalizing nonmonotonic inference has progressed rapidly since its beginnings in the 1970s, and there is now a large body of mature work in the area, much of it highly technical in character. (For a collection of seminal papers, see Ginsberg, 1987; for surveys of the field, see Brewka *et al.*, 1997, and the articles in Gabbay *et al.*, 1994. Antoniou, 1997, offers a relatively accessible introduction to the area.)

One of the most important nonmonotonic formalisms is *default logic*, developed by Raymond Reiter (1980). This involves supplementing first-order logic with new rules of inference called *default rules*, which have the form in (1).

$$(1) \frac{p : q}{r}$$

P is known as the *prerequisite*, q as the *justification*, and r as the *consequent*. Such rules are to be read, 'If p , and if it is consistent with the rest of what is known to assume that q , then conclude that r .' In simpler cases ('normal defaults'), q and r are the same, so the rule says that given the prerequisite, the consequent can be inferred, provided it is consistent with the rest of one's data. Thus the rule that birds typically fly would be represented as (2).

$$(2) \frac{Bird(x) : Flies(x)}{Flies(x)}$$

This says that if x is a bird and the claim that x flies is consistent with what we know, then we can infer that x flies. Given that all we know about Tweety is that he is a bird, we can therefore infer that he flies. The inference is nonmonotonic, since if we subsequently acquire information that is inconsistent with the claim that Tweety flies, then the rule will cease to apply to him.

The application of default rules is tricky, since it is necessary to check their justifications for consistency not only with one's initial data but also with the consequents of any other default rules that may be applied. The application of one rule may thus block that of another. To solve this problem, Reiter introduced the notion of an *extension* for a *default theory*. A default theory consists of a set of premises W and a set of default rules D . An extension for a default theory is a set of sentences E that can be derived from W by applying as many of the rules in D as possible (together with the rules of deductive inference) without generating inconsistency. An extension of a default theory can be thought of as a reasonable development of it.

Another approach, one closely related to default logic, is *autoepistemic logic* (Moore, 1985). This turns

on the idea that we can infer things about the world from our introspective knowledge of our own minds (hence the term 'autoepistemic'). From the fact that I do not believe that I owe you a million pounds, I can infer that I do not owe you a million pounds, since I would surely know if I did. Building on this idea, autoepistemic logic represents rules of thumb as implications of claims about one's own ignorance. For example, the rule that birds typically fly can be represented as the conditional claim that if something is a bird and one does not believe that it *cannot* fly, then it does fly. Given introspective abilities, one can use this claim to draw the defeasible conclusion that Tweety flies, based on one's ignorance of reasons to think he cannot. This approach can be formalized by using the apparatus of modal logic, with the modal operator L interpreted as 'It is believed that.'

A third approach is *circumscription* (McCarthy, 1980, 1986; see also Lifschitz, 1994). This involves formulating rules of thumb with abnormality predicates and then restricting the extension of these predicates – *circumscribing* them – so that they apply to only those things to which they must apply, given the information currently available. Take the Tweety case again. We render the rule of thumb that birds typically fly as the conditional in (3), where 'Abnormal' signifies abnormality with respect to flying ability.

$$(3) \forall x (Bird(x) \ \& \ \neg Abnormal(x) \rightarrow Flies(x)).$$

This does not, of course, allow us to infer that Tweety flies, since we do not know that he is not abnormal with respect to flying ability. But if we add axioms that circumscribe the abnormality predicate so that it applies to only those things that are currently known to be abnormal in this way, then the inference can be drawn. This inference is nonmonotonic, since if we were to add the premise that Tweety *is* abnormal with respect to flying ability, then the extension of the circumscribed predicate would expand to include Tweety, and the inference would no longer go through. Unlike the other strategies mentioned, circumscription can be formulated by using only the resources of first-order predicate calculus, though its full development requires the use of second-order logic, allowing quantification over predicates.

Each of these approaches has its own strengths and weaknesses, but there are some general issues that affect them all. One problem is that all of them allow for the derivation of multiple incompatible sets of conclusions from the same premises. In default logic, for example, a theory may have different extensions depending on the order in

which the rules are applied. The standard example is the theory that consists of the premises *Nixon is a Quaker* and *Nixon is a Republican*, together with the default rules *Quakers are typically pacifists* and *Republicans are typically not pacifists*. Each of these rules blocks the application of the other, since the consequent of one is incompatible with the justification of the other. The theory thus has two incompatible extensions – one in which the first rule is applied and containing the conclusion that Nixon is a pacifist, the other in which the second rule is applied and containing the conclusion that Nixon is not a pacifist. Similar results occur with the other approaches mentioned.

The existence of multiple extensions is not in itself a weakness – indeed, it can be seen as a strength. We might regard each extension as a reasonable extrapolation from the premises and simply plump for one of them. (This is known as the *credulous* strategy. The alternative *skeptical* strategy is to endorse only those claims that appear in every extension.) In some cases, however – particularly in reasoning involving time and causality – a plausible theory generates an unacceptable extension. Much work has been devoted to this problem – one strategy being to set priorities among default rules, which determine the order in which they are applied and so restrict the conclusions that can be drawn. (A much-discussed case is the *Yale shooting problem*, introduced in Hanks and McDermott, 1987, where the rule of thumb that living things typically stay alive generates an unexpected conclusion in reasoning about the effects of using a firearm. For a description of the scenario, see **Frame Problem**, and for discussion, see Shanahan, 1997.)

A second problem concerns implementation. The goal of much work in this area is to build artificial nonmonotonic reasoning systems, but the formal approaches that have been devised are not easy to implement. Default logic, for example, requires checking sets of sentences for consistency, and there is no general procedure for computing such checks. Restricted applications have been devised, however, and aspects of nonmonotonic reasoning have been effectively implemented by using the techniques of *logic programming* (programming in languages based on formal logic).

A third issue concerns the piecemeal character of much work in this area. Theories have been developed and elaborated in response to particular problem cases and with relatively little attention to the features of the inference relations they generate. Recent work has begun to address this issue and to identify properties that are desirable in any nonmonotonic inference relation (see, for example, Makinson, 1994). One of

these is that adding a conclusion back into the premise set should not undermine any other conclusions – a property known as *cautious monotonicity*.

Finally, a word about probabilistic logics. Most nonmonotonic formalisms embody a *qualitative* approach: premises and conclusions are treated as either true or false, as in deductive logic. But probabilistic logics, in which propositions are assigned continuous probability values, can also be used to model certain types of nonmonotonic inference. In probabilistic reasoning, it is common to treat a conclusion as warranted if its probability, given the premises, exceeds a certain threshold. This inference relation is nonmonotonic, since the addition of new premises may lead to a readjustment of one's probability assignments, with the result that a conclusion that previously passed the threshold now falls short of it. However, although probabilistic logics are well suited for modeling reasoning under uncertainty (see Shafer and Pearl, 1990), it is unlikely that they can do all the work required of a theory of nonmonotonic inference (McCarthy, 1986).

Nonstandard Language Use

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

To talk of *non-standard* language use presupposes that we understand what it is for a use of language to be *standard*. A standard use can be thought of either as a use that conforms to some standard (viz. to a linguistic rule or convention) or as a use that is the usual or most common one. So, a non-standard use is either one that flouts a linguistic convention or that is an uncommon or novel use. Various linguistic phenomena somehow marked as non-standard will be discussed and classified as belonging to one or another of these two categories of non-standard usage. A possible third sense of ‘non-standard,’ which is the opposite of Bach’s (1995) notion of a *standardized* use, also will be discussed. Although non-standardized uses may be *pragmatically marked* uses of expressions, they don’t flout linguistic conventions and are not novel. Speech errors, such as cases in which a speaker says ‘pig vat’ instead of ‘big fat,’ also could be viewed as cases of non-standard language use, but will not be discussed in this article.

A conventional use, one conforming to a linguistic convention, is an agreed-upon use. The agreement needn’t be an explicit one but simply a matter of members of a linguistic community conforming their use to that of other members of the community, so long as others do the same. Malapropisms are one sort of example of *non-conventional* use. Malapropisms are cases where a speaker (unintentionally) substitutes a word for another word, whose agreed-upon meaning is different from what the speaker intends to convey. Usually the substitution is based on some sort of sound similarity between the ‘correct’ and ‘incorrect’ usage.

In his play *The Rivals*, Richard Sheridan has a lot of fun at the expense of his character Mrs. Malaprop. For example, Mrs. Malaprop exclaims to Sir Anthony Absolute, ‘you surely speak laconically!’, meaning to

surmise that Sir Anthony is speaking ironically. A little later she hopes that Sir Anthony will regard her niece, Lydia Languish, ‘as an object not altogether illegible,’ meaning that she hopes her niece will not be regarded as someone ineligible for a match with Sir Anthony’s son.

Such malapropisms are not confined to fiction. For example, in some experimental work on referential communication reported by Brown (1995), a participant in a map-reading task referred to an electric pylon as a colon. Another example occurred on the June 16, 2004, broadcast of the Tavis Smiley Show on National Public Radio. One of Smiley’s guests praised him by saying, ‘You have spoken up so unanimously for black people.’ The concept of unanimity only makes sense when one is talking about a group of people, and Smiley is a single individual. However, what the guest was thinking is that whenever Smiley speaks up he speaks up for black people. So, if one thinks of Smiley and his past selves as a group, one can think of them as speaking with one voice and hence as unanimous. This last example shows that malapropisms are not always based on *sound* similarities but can arise from quite complicated cognitive comparisons (e.g., Smiley and his past selves are like a group of individuals).

Malapropisms are extreme examples of misuse, and rather idiosyncratic. There are other examples of ‘misuse’ that are more widespread among members of a linguistic community. For example, many people use the sentence, ‘Hopefully, Bush will be defeated’ to express their hope that Bush will be defeated, not the thought that the defeating of Bush will be performed with hope. Or again, many people say things such as, ‘Me and him are going to the movies’ or ‘I could care less’ or ‘Everyone will be bringing their spouses’ instead of ‘He and I are going to the movies’ or ‘I couldn’t care less’ or ‘Everyone will be bringing his or her spouse.’

Given how widespread these latter ‘misuses’ are, one might argue that, rather than being misuses of English, they are acceptable uses within some

'non-standard' dialects of English. Calling these dialectal varieties 'non-standard' is rather contentious. There are some language purists who argue that only 'standard' English is acceptable usage. However, as Chomsky (2000) points out, calling some varieties of English 'standard' and regarding them as normative for English usage generally has nothing to do with the linguistic properties of these language varieties, but is purely a matter of power politics. The dialect of the ruling group is inevitably regarded as the norm for correct speech. Everyone has heard the old saw about a language being a dialect with an army and a navy. But as Chomsky remarks: "To say that one variety of English is 'right' and another 'wrong' makes as much sense as saying that Spanish is right and English is wrong" (2000: 71).

According to the second sense of 'non-standard' articulated above, non-standard uses are novel or 'nonce,' i.e., one-off, uses. The largest class of uses that have been thought of as 'nonce' are the uses of sentences to convey Gricean *particularized* conversational implicatures. For instance, a mother asks her teenage son to tidy his room and he replies: 'I have to beat this boss real quick.' The son is explicitly talking about what he has to do in the video game he's playing but is implicitly refusing to clean his room right then. In this sense of 'nonce' meaning, the novel meaning is something that is merely *indirectly* or *implicitly* conveyed. Such nonce meanings are conveyed because the hearer understands the speaker to have explicitly said one thing but to have meant something else (either in addition or instead). Thus, implicatures are not nonce meanings *for expressions*. Rather, they are novel meanings conveyed *by* the use of expressions that are understood to have their conventional meanings.

Metaphorical, ironic, metonymic, and other such 'non-literal' uses of expressions have also been thought of as nonce uses. For example, 'The soldiers butchered the villagers' can be used metaphorically to express the fact that the soldiers killed the villagers in a particularly inhumane way. 'You're a fine friend' can be used ironically to express the fact that the hearer has done something unfriendly. 'The ham sandwich is getting restless' can be used metonymically to express the fact that the orderer of the ham sandwich is getting restless. Many philosophers analyze such uses in terms of Gricean particularized conversational implicatures. The speaker says one thing but indirectly conveys something else. Inasmuch as such uses are analyzed in Gricean terms, these again would not be cases in which *expressions* are given novel meanings. Rather, *by* using expressions with their conventional meanings, speakers *indirectly* express novel meanings.

(Of course, the examples of metaphor, irony, and metonymy given above are very hackneyed, and in

this sense are not 'novel.' For example, the 'butcher' metaphor has become a 'dead' metaphor. Many dictionaries of English usage now list 'to kill in a brutal manner' as one of the meanings of 'to butcher.' Other, 'fresher,' examples could have been given, but these would have required more context setting.)

Not everyone would agree that cases of metaphor and metonymy are correctly analyzed in Gricean terms. An alternative 'contextualist' view denies that we interpret the entire sentence literally and only then (because of a violation of some Gricean maxim, such as the maxim of quality) derive an implicated metaphorical meaning. For example, consider the following

- (1) Dickens is easy to read.
- (2) The appendectomy is on top of the cabinet.
- (3) The stinkbug has left the room.

In (1), which is an example of a producer-for-product metonymy, 'Dickens' is used to refer to the novels that Dickens wrote. In (2), one can imagine a context in which 'the appendectomy' is used to refer to the file of the patient who is scheduled for an appendectomy. And in (3), 'the stinkbug' can be used metaphorically to refer to a person whose personal hygiene leaves much to be desired. According to the contextualist, local pragmatic processes operate on the referring terms ('Dickens,' 'the appendectomy,' 'the stinkbug') to yield pragmatically determined contents. These become a part of the propositional contents that are directly expressed by sentences (1)–(3) in their conversational contexts. For example, the speaker of (2) doesn't say falsely that a medical procedure is on the cabinet and thereby indirectly convey the proposition that the file of a patient scheduled for an appendectomy is on the cabinet. Rather, the latter proposition is directly expressed. See Carston (1997) and Bezuidenhout (2001) for a defense of the contextualist view of metaphor.

If this view is correct, there is a sense in which the expressions 'Dickens,' 'the appendectomy,' etc. are given novel meanings in different contexts. These novel meanings are not merely indirectly conveyed *by* literally saying something else. Note, this view is *not* committed to a 'Humpty Dumpty' theory of meaning, according to which expressions can mean whatever their users intend them to mean. (In *Through the Looking-Glass*, Humpty Dumpty says to Alice, 'There's glory for you' and claims to mean 'There's a nice knockdown argument for you.') According to the contextualist view, the novel contextual meanings of expressions are pragmatic developments of semantically encoded meanings. The local pragmatic processes that determine contextual meanings are thus not completely unconstrained.

Speakers cannot convey novel meanings that are completely unrelated to conventionally encoded meanings. (For a more radical view, see Donnellan [1968] and Davidson [1986]. They argue that, in appropriate contexts, 'glory' *can* mean *a nice knock-down argument*.)

Another class of uses that have been called 'nonce' are ones in which speakers coin new words. Attested examples are as follows, the first two given by Clark (1992: 315–316), the third by Higginbotham (2002: 577):

- (4) He's being grand juried for possible conflict in real estate loans.
- (5) Today I'm going gallerying.
- (6) I've hard-driven the diskette.

These novel uses are similar to ones that have already entered common usage, such as 'He docked the boat' or 'The librarian shelved the books.' These uses all obey a productive rule, in which a noun is turned into a verb by the addition of a verbal particle ('-ed' to signal past tense, '-ing' to signal an ongoing or incomplete action). The novel words are coined because there is no readily available, short expression already in common use that quite covers the speaker's intended meaning.

In some cases, people invent new words when there are already perfectly good words in common usage that mean exactly what the speaker intends. For example, on the June 16, 2004, edition of the *Tavis Smiley Show* on NPR, one of Smiley's guests said: 'You have to converse and talk to your child on a man to man level.' Presumably what was meant was that one should *converse* with one's child. What is already a verb, 'to converse,' is subjected to a morphological rule for verb formation, by the addition of the suffix '-ate,' perhaps on analogy with the verb 'to orientate,' which is frequently used instead of the plain 'to orient' (this latter being the norm in standard American English, although not in standard British English, which favors 'to orientate').

A third sense of 'standard use' should be mentioned. It corresponds to what Bach (1995) calls a *standardized* use, which he distinguishes from a conventional use. One reason that Bach appeals to his notion of standardized use is to counter attempts by relevance theorists such as Carston (1995) to reconstrue Gricean *generalized* conversational implicatures as part of what is directly expressed. Consider, for example, the Gricean treatment of scalar terms, such as numerals. On this view, 'Grice has three teeth' literally says that Grice has *at least* three teeth, but it conversationally implicates in a generalized way that Grice has *at most* three teeth. These two propositions

together entail that Grice has *exactly* three teeth. Carston's alternative view is that 'three teeth' is semantically underspecified. When used in an appropriate context, it can be specified in such a way that what is said (i.e., what is explicitly conveyed) in that context by 'Grice has three teeth' is that *Grice has exactly three teeth*.

Bach offers a third alternative. On this view, 'three teeth' has a standardized use to convey *exactly three teeth*. A standardized use is something like a default use. It is a default in the sense that it has become a regular practice – perhaps a mental habit – for members of the linguistic community to use the word(s) in question in a certain way, given that circumstances are normal. Only if circumstances are somehow unusual will a different interpretation be called for. Bach denies that the standardized meaning is explicitly conveyed. It is implicitly conveyed (he calls it an 'implicature'), but because it is conveyed by default in normal circumstances, it gives the illusion of being directly conveyed. The inference that is needed to derive this standardized interpretation has become compressed by precedent. Hence, hearers are not aware of having made any inference. A similar view, according to which generalized implicatures are default inferences, has been defended by Levinson (2000).

The details of Bach's views are not important here. The main point is to introduce a third sense of 'non-standard use.' It corresponds to a *non-standardized* use in Bach's sense. A non-standardized use is one that is called for when circumstances are somehow not 'normal' and hence the default meaning must be overridden. For instance, suppose Grice has a large collection of shark teeth and you need exactly three shark teeth for an artwork you are creating. Believing that Grice might be willing to give up some of his shark teeth for you I say 'Grice has three teeth.' Arguably what is conveyed here is that Grice has at least three teeth, not that he has exactly three. Now, according to Griceans such as Bach and Levinson, the conventionally encoded meaning of 'three teeth' is *at least three teeth*. In other words, when circumstances are *not* normal and the default meaning is overridden, the meaning that is conveyed is the literally encoded meaning. So the non-standardized use in this case is the conventional one (i.e., it is a standard use in the first sense articulated above).

In the example given in the previous paragraph, pragmatic context indicated that a non-default understanding of 'three teeth' was called for. Sometimes, however, the linguistic expression itself signals whether it is to be given a default or non-default reading. There are pragmatically marked and unmarked ways of saying things. Unmarked ways of

saying things call for default interpretations. Marked ways of saying things call for non-default interpretations. For example, there is a difference between saying 'The policeman stopped the car' and 'The policeman brought the car to a stop.' The former suggests that the stopping was the normal sort of stopping, whereas the latter suggests that the policeman did something unusual to halt the car. But although non-standardized uses may be *pragmatically marked* uses of expressions, they don't flout linguistic conventions and they are not novel uses, or at least no more novel than their unmarked alternatives. Both 'The policeman stopped the car' and 'The policeman brought the car to a stop' will call for quite a lot of pragmatic inferencing to understand what the speaker said.

Normativity

S Gross, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Normative claims concern the ways things should be. Nonnormative (or descriptive) claims concern how things are, which can diverge from how they should be. 'No one should speed' is a normative claim; 'they are speeding' is not. Neither is '85% of drivers speed,' even if it describes how things in fact normally are. Statistical norms must be distinguished from norms or standards for how things ought to be.

In exploring the relevance of normativity to language, it is useful to bear in mind that normative claims fall into various kinds and can possess a range of further features. Consider the following examples:

1. Sheets should be clean.
2. Friends should not spread gossip.
3. Smoking is permitted.
4. If you believe some claim, you shouldn't believe its negation.
5. Only goalkeepers may touch the ball with their hands.

6. Goalkeepers should avoid straying from their goal.
7. Pedestrians may cross only at the crosswalk.
8. You shouldn't wear blue slacks with a brown jacket.
9. If you want to improve, you should practice more.

These examples illustrate a variety of features of normativity. Normative claims may state, not only how things should be (1), but also how they should *not* be (2), as well as how they are allowed though not necessarily required to be (3). The subject of norms can include agents (2), actions (3), and states of affairs (1). Normative claims can be conditional (4). The applicability of a norm may be constitutive of an activity ((5) – one is not playing soccer if players may use their hands). Or it may just be constitutive of doing it well (6). Normative claims are not restricted to moral claims; they can be legal (7), aesthetic (8); means–end (9); etc.

Issues involving normativity arise regarding language and linguistics in a variety of ways. Four particularly prominent questions are discussed below: May linguistics itself issue normative pronouncements concerning language and language use? Are semantic

properties inherently normative? Are speech acts and pragmatic phenomena more generally inherently normative? What linguistic properties do the terms used to express normative claims themselves have?

Prescriptive Versus Descriptive Linguistics

Language users often turn to dictionaries to answer questions concerning how a word should be used. They view dictionaries as compendia of prescriptions, not descriptions. Linguists, however, generally do not aspire to normative conclusions in their research. They aim to describe and explain linguistic phenomena. On their view, linguistics, at least as they practice it, is and ought to be an empirical science. To the normative question ‘what sort of pursuit should linguistics be?’ they thus provide an answer that eschews normativity so far as the pronouncements of linguistics are concerned (see **Description and Prescription**).

It is a distinct question, however, whether the scientific study of language, though it should not enter normative claims, must also prescind from examining and adverting to normative phenomena. Canons of politeness, for example, are normative. But they impact language and language use. For instance, they affect turn-taking in discourse and can become lexically, morphologically, and syntactically encoded. They thus seem important objects of study for linguists. Some philosophers of science suggest that naturalistic inquiry cannot accommodate intrinsically normative phenomena. Others object that this represents an overly narrow conception of naturalistic inquiry. This is an instance of a larger (venerable) debate concerning the status of the ‘human’ (or, social) sciences and their relation to the natural sciences (cf. Martin and McIntyre, 1994: Part III).

Semantics and Normativity

It is often claimed that semantic properties are intrinsically normative, in some manner encoding standards of correctness. Though fleshed out in various ways, the defense typically involves arguments purporting to show that the possession of a semantic property entails or is entailed by something normative.

For example, it is sometimes suggested that, if ‘dog’ denotes dogs, then one ought to apply the term only to dogs. If one applies the term to a cat, one has made a mistake (cf. Kripke, 1982). Here, it is claimed that possession of a semantic property has normative consequences. However, it is not generally the case that,

if one should or should not do something with an X, then Xs are intrinsically normative; one ought not throw rocks at people, but rocks are not intrinsically normative – nor is the property of being a rock or any of a rock’s intrinsic properties. What matters is whether the normative conclusion follows *just* from the thing’s being X. That one should not throw rocks at people follows, not just from what rocks are like, but from that and one’s obligation not to cause bodily harm.

The question is thus whether the possession of a semantic property like ‘denotes dogs’ is sufficient in and of itself to generate obligations. Arguably, it is not: that one ought to apply ‘dog’ only to dogs would seem to follow, not just from its possessing the semantic property of denoting dogs, but from that and the further assumption that one ought to aim at truth. Perhaps one indeed ought to aim at truth; perhaps not always (maybe there are circumstances in which lying is justified – for example, to confuse a would-be cat-killer). But if the assumption that one should aim at truth must be added, then the normative conclusion does not follow from the semantic claim alone (Horwich, 1998: Chapter 8).

Others claim that semantic properties are intrinsically normative because *what makes it the case* that terms have their semantic properties are certain normative phenomena. The possession of semantic properties is thus alleged to be entailed or determined by the obtaining of normative facts. For example, some argue that semantic claims (such as that ‘dog’ denotes dogs) obtain in virtue of a language user’s being disposed to apply ‘dog’ to dogs in appropriate circumstances – where what makes circumstances appropriate may include how things optimally ought to be when applying such a term. Others, however, attempt to show that, contrary to such claims, one can ‘naturalize’ semantic content. They maintain that terms have their semantic properties in virtue of facts that can be characterized nonnormatively (cf. Loewer, 1996).

One project in foundational semantics that would reject ‘naturalization’ thus construed is inferentialism (Brandom, 1994). According to it, semantic claims (such as ‘dog’ denotes dogs) obtain in virtue of it being the case that certain inferences involving the term would be correct to draw, and certain inferences would not. Logical terms provide the best cases for this approach: the claim would be that ‘and’ means what it does in virtue of the validity of inferences of the form (1) ‘A and B’ implies A and (2) A, B implies ‘A and B.’ Among the challenges is to extend this strategy to other terms. In the case of ‘dog,’ the relevant inferences would include not only transitions (in appropriate circumstances) from the presence of dogs

to ‘Those are dogs,’ but also the inference from ‘Those are dogs’ to ‘Those are mammals’ – and much more besides.

Pragmatics and Normativity

Even if the meanings of expressions are not inherently normative, one might claim that what speakers do with expressions is inherently normative. Human language use, at least in core cases, is a species of intentional action, and all such action is done for reasons. One’s reasons for acting are subject to normative assessment; they may or may not be *good* reasons. The intentional nature of linguistic action figures prominently in speech act theory (Austin, 1975) and accounts of conversational implicature (Grice, 1989). It also provides one motivation for developing game-theoretic models of language use.

Consider first the study of speech acts. It is often claimed that, for the utterance of a sentence to constitute the performance of a speech act, it must be performed intentionally by a speaker beholden to certain norms, with specific norms attaching to specific speech acts. For example, for the utterance of a particular sentence to constitute an assertion, the speaker must represent herself as having warrant for the truth of the claim asserted, with the result that she can be held accountable if the claim is not true or at least was not asserted on sufficient grounds. The transmission of truth, or perhaps knowledge, is said to be the aim or point of the practice of assertion. In this case, the norms constraining linguistic action would be constitutive of the kind of action at issue (cf. Williamson, 1996).

In performing a specific speech act such as assertion, it is often one’s intention to communicate more than just what one asserts. (Sometimes one intends to communicate something *instead* of what one makes as if to assert.) For example, in answer to the question ‘Do you think John is coming?’ one might utter the sentence ‘There’s a lot of snow on the roads’ in order both to assert that there’s a lot of snow on the roads and to communicate that John is probably not coming. Grice (1989) argued that such ‘conversational implicatures’ are possible because of language users’ sensitivity to the reasons for which a cooperative speaker would utter particular sentences in particular conversational contexts. He articulated a set of maxims for cooperative language use – for example, that one be as informative as possible, all else being equal, but also that one refrain from prolixity, all else being equal – that parties to a conversation tacitly assume one another to be observing. Speakers can then rely on hearers to infer an implicature, as in the case above, when doing so preserves the assumption of

cooperation. Such maxims are norms that specifically apply to cooperative conversations and that enable speakers and hearers to discern the specific conversational reasons behind linguistic actions.

In the preceding discussion, statistical norms were sharply distinguished from norms for how things ought to be. But statistical norms, like other nonnormative facts, can have normative upshot; how things are affects what means one should take to achieve one’s ends. Conforming to a trend, for example, can in some cases increase the likelihood of obtaining an outcome. This is certainly so with language. Suppose one has an interest in one’s utterances being understood. One then has reason to speak in a way that will promote understanding. But then, insofar as there exist statistical norms concerning pronunciation, assignment of meaning, expected prolixity, and other linguistic matters, there is reason to conform to those norms, since those norms will correlate with other language users’ expectations. This provides one rationale for using game-theoretic techniques to study both the development of linguistic norms (in the statistical sense) and the ways speakers deploy language on particular occasions (see, e.g., Nowak and Komarova 2001, and with reference to pragmatic phenomena, Parikh, 2001).

Linguistic Properties of Normative Terms

We express normative claims – like any other claims – by using language. Normative expressions such as ‘ought,’ ‘justified,’ and ‘you should not do that’ are thus themselves proper objects of linguistic theorizing. Three examples are the use of deontic logic to capture the content of normative lexical items, expressivism as a non-truth-conditional analysis of normative sentences, and the study of generics.

Deontic logic – a branch of intensional logic – studies the logical relationships among normative expressions. ‘It’s obligatory that one X,’ for example, implies ‘It’s not forbidden that one X.’ Logicians studying such expressions construct formal languages with axioms and inference rules that capture these relations. Such investigations can be construed as contributions to the lexical semantics of the normative terms (see Føllesdal and Hilpinen, 1971).

Expressivism in its most basic form is the doctrine that normative claims such as ‘Murder is wrong’ do not purport to determine truth-conditions, but rather express an attitude toward a certain kind of action – in this case a negative attitude toward murder. Normative claims on this view are thus no more liable to assessment for truth or falsity than such aesthetic expressions as ‘Chocolate: yum!’ Expressivism might

be motivated by the intuition that normative claims – for example, moral claims – do not purport to express objective facts. Expressivism, however, has difficulty accommodating embedded normative claims. The sentence ‘If murder is wrong, then what Mary did was wrong’ does not itself express any attitude to murder. This would seem to indicate that the expression of an attitude is not itself among the semantic properties of the expressions used. Moreover, the following argument seems deductively valid: murder is wrong; if murder is wrong, then what Mary did was wrong; therefore, what Mary did was wrong. It’s natural to elucidate this validity by viewing the argument as an instance of the truth-preserving inference schema *Modus Ponens*. But this can seem blocked if normative claims do not determine truth-conditions. (For discussion from the perspective of a more sophisticated version of expressivism, see Gibbard, 2003.)

Generic claims – such as ‘Dogs have four legs’ – provide an example of unobvious normativity. The sample sentence’s truth, on the relevant reading, does not depend on the four-leggedness of *all* dogs. (Amputees do not witness its falsity.) Nor does the existence of *some* four-legged dogs suffice for its truth. The claim is not even that *most* dogs have four legs: a generic claim does not report a statistical norm. (It may be true that a spider’s life has four stages, even if the vast majority of spiders never make it past the first.) The content of a generic claim is rather normative; *normal* dogs have four legs. Perhaps this is even in some sense how dogs ought to be – at least to conform to conversationally relevant expectations. (On generics generally, see Carlson and Pelletier, 1995.)

Object-Dependent Thoughts

S Crawford, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Some of our thoughts involve reference to particular individual entities. Philosophers call these kinds of thoughts ‘singular thoughts.’ *Russell was a great philosopher, you’re standing on my foot, I’m tired, that raccoon got into my garbage last night* – these are all singular thoughts because each involves reference to a particular thing: Russell, you, me, and a certain raccoon, respectively. As these examples indicate, singular thoughts are usually expressed by sentences containing proper names (e.g., ‘Russell’), indexicals (e.g., ‘you’ and ‘I’), and demonstrative expressions (e.g., ‘that raccoon’).

Singular Thoughts as Object Dependent

Some philosophers maintain that singular thoughts are *object dependent*, by which they mean that the intentional content of the thought essentially involves the object that it is about, in the sense that the thought content would not be available to a thinker were the object not to exist. More precisely, a singular thought is object dependent just in case its content is such that (1) its existence depends on the existence of the object thought about, and (2) its identity depends on the identity of the object thought about. For example, consider the thought *that raccoon got into my garbage last night*, had by me while spying a particular raccoon skulking in my backyard. According to the doctrine of object dependence, if, counterfactually, no raccoon had in fact been there to be singled out by me, owing perhaps to my delusional or hallucinatory state of mind – let us call this the “empty possibility” – then there would have been no singular thought content for me to entertain. Consequently, my psychological condition in this situation would be different from what it is in the actual situation. Moreover, if, counterfactually, my thought had singled out a qualitatively indistinguishable but numerically different raccoon instead – call this the “duplicate possibility” – then the resulting thought would have had a different

content from the content that my thought had in the actual situation. Again, my overall psychological state in this duplicate possibility is different from what it actually is. The implication here for linguistic meaning is that the meaning of sentences containing genuine singular terms (e.g., proper names, indexicals, and demonstrative expressions) depends on the singular terms in question successfully referring to objects. On this view, nonfictional sentences containing non-referring singular terms, such as empty or bearerless names, are meaningless, in the sense that they fail to express any thoughts.

The doctrine of object dependence is a species of the more general doctrine of *externalism* about thought content, according to which some states of mind are such that we can be in them only if we bear certain appropriate relations to other things in our environment, and thus is opposed to *internalism* about the mind, according to which the contents of our thoughts are never dependent on any relations between us and other things in our environment. (Some philosophers, such as Burge [1982], accept the general doctrine of externalism but reject object dependence.)

Epistemological Consequences of Object-Dependence

It is controversial which, if any, singular thoughts are object dependent. Arguably, first-person thoughts expressed with the indexical ‘I’ are object dependent: it seems obvious that if I did not exist, then the thought that I now express with the sentence *I’m tired* could not exist; moreover, no one else could have had the very same thought. But the thesis that singular thoughts expressed with proper names and demonstratives are object dependent has seemed paradoxical to some philosophers. For when the idea of object dependence is applied to these other types of singular thoughts, it runs up against a strongly held intuition about the nature of thought content, namely, that we have a kind of direct, noninferential knowledge of the contents of our thoughts, in the sense that we know, just by thinking, whether we are having a thought and, moreover, what thought we are having.

The doctrine of object dependence seems to contravene this intuition about the epistemology of thought.

For, first of all, condition (1) above allows the possibility that a thinker could suffer the illusion of entertaining a thought when he was not in fact doing so. If, unbeknown to me, I am in what we have been calling an empty possibility and am hallucinating a raccoon rather than actually seeing one, it may seem to me that I am having a singular thought, which I might try to express with the sentence *that raccoon got into my garbage last night*, even though I am not. But is this kind of cognitive illusion really possible? It is very tempting to think, against this, that if it seems to me as if I am having a thought with a certain content, then I am. Perhaps I might be mistaken about which object, if any, my thought is about – but how could I be mistaken about whether I was even thinking a thought at all?

Condition (2) has also seemed problematic. Consider what we have called the duplicate counterfactual possibility, in which I see a different raccoon, qualitatively indistinguishable from the one I actually see, and think *that raccoon got into my garbage last night*. In such a case, everything will seem the same to me: the duplicate raccoon does not appear to affect my conscious awareness in any way different from how the actual raccoon affects it. But is not subjective indistinguishability the criterion for sameness and difference of thought content? Opponents of object dependence argue that in order for there to be a genuinely psychological or mental difference between the two cases, this difference must impinge on my conscious awareness in some way. The object-dependent theorist denies this, arguing that it is the product of a mistaken internalist picture of the mind, a picture that the object-dependent theorist urges us to reject in favor of an externalist view. The debate between object-dependent theorists and their opponents is thus linked to a certain extent to the larger debate between internalism and externalism about thought content.

The Central Motivation for Object Dependence

A number of different considerations have been advanced in favor of an object-dependent conception of singular thought, and many involve a synthesis of key ideas of Frege and Russell (Evans, 1982; McDowell, 1977, 1984, 1986; McCulloch, 1989). Advocates of this form of object dependence are often labeled ‘neo-Fregeans,’ which can be confusing, because object-dependent singular thoughts are also often called ‘Russellian thoughts,’ so one needs to be aware of differing terminology here.

Perhaps the best way to appreciate the object-dependent theorists’ point of view is to begin by noting that they do countenance thoughts that in a certain sense concern particular individuals but that would be available to a thinker were those individuals not to exist. Moreover, there is a straightforward sense in which the contents of these kinds of thoughts would remain unaffected were duplicate objects substituted for the actual ones. Calling these kinds of thoughts object-independent thoughts, we can say that although they concern particulars, the relation between their contents and their objects is much less direct or intimate than the relation between the contents and objects of object-dependent thoughts (the idea goes back to Russell’s seminal distinction [1910–1911] between knowledge by description and knowledge by acquaintance).

The most obvious examples of object-independent thoughts are thoughts that involve definite description concepts, thoughts of the form *the F is G*. Consider the thought *the first man on the moon was an American*. As it happens, this thought is about Neil Armstrong because he was in fact the first man on the moon. But consider now the empty possibility in which the lunar landing was a hoax and the definite description *the first man on the moon* fails to designate anything. The object-dependent theorist holds that even though the thought fails to single out any actual object in the world, the thought still has a content, a content expressed, in part, by the definite description. Similarly, consider the duplicate possibility, in which Neil Armstrong’s identical twin is the first man on the moon. Despite the thought’s picking out a different man, the content of the thought remains the same – again, that expressed (in part) by the definite description *the first man on the moon*. The crucial point here is that the intentional content of the thought can be specified independently of the object, if any, that it is about.

The object-dependent theorist’s idea is this. Thought content is essentially representational: it represents the world as being a certain way; it lays down conditions that the world must meet in order for the thought to be true. That is to say, the content of a thought determines its truth conditions. In the case of a thought employing a definite description concept *the F* (a descriptive thought, for short), the thinker knows what those conditions are without knowing which object, if any, the thought concerns. If I say to you *the first man on the moon was American*, it is not necessary for you to know which object is the first man on the moon, nor even that there is such an object, in order for you to understand what I have said, in order for you to “grasp” the thought I expressed with this sentence. So long as

you understand all the words in the sentence and their mode of combination, you know exactly how the world is represented as being; you know what the thought is “saying” about reality. In other words, you know that the thought is true just in case there is a unique man who was first on the moon and who was American. It does not matter who this man happens to be – Neil Armstrong, his identical twin, or Buzz Aldrin. So long as there is such a man, the thought is true; and if there is no such man – either because no man at all has ever been on the moon or because more than one man stepped onto the moon at exactly the same time – then the thought is false. The representational content of a descriptive thought is thus independent of any object that the content might be about. The truth conditions make no reference to any man in particular.

When it comes to singular thoughts, however, the object-dependent theorist maintains that their representational content is not independent of any object the content is about. On the contrary, the content requires that a certain particular object be picked out. In order to understand or grasp the thought in question, one must know which particular object this is. Consider the foregoing example of a singular thought: *that raccoon got into my garbage last night*, based on my visual experience of a particular raccoon in my backyard (these kinds of singular thoughts are sometimes called ‘perceptual demonstrative thoughts’). Now, in having this thought, I am representing the world in a certain way. What way is this exactly? Well, I am not representing the world as merely containing a raccoon that got into my garbage last night, whichever raccoon that might be. The way I am representing the world as being involves that very raccoon. My thought is true just in case that raccoon (the very one I saw) got into my garbage last night; and in order for you to have this thought too, you need to know which particular raccoon is singled out by my perceptual demonstrative ‘that raccoon.’ Contrast this with the very different case in which I think the descriptive thought *the cleverest and boldest raccoon in the neighborhood got into my garbage last night*. All that it takes for this thought to be true is for there to be a unique raccoon, who is cleverer and bolder than all the rest and who got into my garbage – and you can grasp this thought without knowing which raccoon, if any, that was. If it turns out that there was no such raccoon, then my thought is straightforwardly false. But the truth conditions for my perceptual demonstrative thought make essential reference to the very object it is about. The truth or falsity of this thought of mine turns on the condition of a particular raccoon, namely, that raccoon – so that if there is no such creature, if (say) I am hallucinating,

there is nothing in the world to count as my thought being true or false. Consequently, in this empty possibility, my mental episode, whatever exactly its nature, has no truth conditions (for, to repeat, there is nothing *of which* I have judged to have a certain property; nor have I made the mere existential claim that there is *an* object with a certain property). Since thought content is essentially truth conditional, according to the object-dependent theorist, I have not in fact had a singular thought at all, only the illusion of one. Whether considerations like these in favor of object dependence apply equally to other kinds of singular thoughts, such as those expressed with proper names and indexicals (other than ‘I’), is a further question.

Criticisms and Rivals

Various criticisms have been leveled at the object-dependent conception of singular thought. Some of these arise from problems that the conception inherits from the general doctrine of externalism, such as its apparent conflict with certain features of self-knowledge (Davies, 1998). Three issues, however, stand out with respect to object dependence in particular.

The first is the question of what is going on, psychologically speaking, in the minds of deluded subjects in empty possibilities who suffer the illusion of entertaining singular thoughts. Their minds are not phenomenological blanks, after all; yet, according to the object-dependent theorist, they are not filled with any singular thoughts. Are such deluded subjects having any thoughts at all? If so, what kinds of thoughts are they having?

The second issue is closely related to the first and concerns the commonsense psychological explanation of the actions of deluded subjects. Normally, we explain agents’ actions – my charging into the backyard, say – by attributing singular thoughts to them – the belief that that raccoon got into my garbage last night, for example. But now consider my deluded duplicate who, after hallucinating a raccoon in the empty possibility, engages in the very same type of behavior of charging into the backyard. According to the object-dependent theorist, my duplicate here has no singular thought; that is, he has no belief the content of which is *that raccoon got into my garbage last night*. But, although he is hallucinating, his action is perfectly rational and so is presumably psychologically explicable by ordinary commonsense standards. But how do we so explain his behavior without attributing a singular thought to him (McDowell, 1977; Segal, 1989)? Moreover, if we can explain his behavior without attributing a singular thought to him, then why can we not do the same with me in the

actual situation? But if we can do this with me too, then it looks as if the ascription of object-dependent singular thoughts is 'psychologically redundant' – and that allegedly calls into question their very existence (Noonan, 1986, 1991; Segal, 1989).

The third issue, perhaps the most serious, is that there are powerful rival object-independent conceptions of singular thought, which are free of many of the problems that beset object-dependent theories. There tend to be two different kinds of alternative conceptions.

The first of these conceptions attempts to analyze singular thought content in wholly general or descriptive terms, in such a way that the same content can exist in duplicate and empty possibilities, in the manner of thoughts involving definite description concepts, discussed earlier (Schiffer, 1978; Searle, 1983, 1991; Blackburn, 1984: chapter 9). For example, we might try to analyze the content of the demonstrative expression *that raccoon* as equivalent to the content of the definite description *the raccoon I am seeing now* or *the raccoon causing this visual experience*.

The second approach opposes this kind of descriptive reduction and maintains a genuinely singular conception of singular thought but argues that a distinction between irreducibly singular (or "*de re*") content and object can still be drawn, again, in such a way that, as with the first alternative, the same singular content can exist in both duplicate and empty possibilities (Burge, 1977, 1982, 1983, 1991; Bach, 1987; Segal, 1989). This approach exploits an analogy between the semantics of sentences containing demonstratives and pronouns (*this is red*, *she is tall*) and the semantics of the open sentences of a logical system (*x is red*, *x is tall*) – namely, that both kinds of sentences are true or false only under an assignment of values to the demonstratives, pronouns, and free variables in question. The proposal is to treat a sentence such as *that is a raccoon* as like a predicate, or open sentence in the logician's sense, and to think of it as expressing a single content (a "propositionally incomplete" content) that is mentally applied, in different situations, to different objects, and even, in some situations, to no object at all.

These two alternatives each face their own difficulties, however. The first alternative seems to overintellectualize thinking. When I think *that raccoon got into my garbage last night*, I do not appear to be thinking about myself or the present moment or about causation or my own visual experiences, and even if I were doing so in a philosophical mood, it does not seem necessary for a creature to have such sophisticated concepts in order for it to have singular thoughts (McDowell, 1991; Burge, 1991; Searle, 1991). As for

the second alternative, it is not clear to what extent it departs from the intuitive principle that thought content is fully representational in the sense of always determining truth conditions. For in the empty counterfactual possibility, in which I hallucinate a raccoon, no value will be assigned to the demonstrative concept in my thought (*that raccoon*), and hence no truth conditions for the overall thought will be determined. The advocates of this second alternative approach thus seem committed to the view that I can have thoughts that possess no truth conditions, something that may give us pause.

Objectivity in Moral Discourse

M Timmons, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Does moral discourse purport to be objective? If so, can its objectivist pretensions be justified? Roughly speaking, to say that some form of discourse is objective is to say that there is a single set of truths about whatever subject matter the discourse is about. We can make this rough characterization more precise by formulating a number of related theses – objectivity theses – that collectively capture this idea of objectivity:

Cognitivism: Declarative sentences of the discourse in question are used by speakers to make genuine assertions and function mainly to express the speaker's beliefs. Given that (sincere) belief and assertion aim at representing what is true, such sentences are capable of being true or false.

Truth: Some affirmative sentences of the discourse are true.

Independence: What makes some sentence of the discourse true is that it corresponds to some fact – where the existence and nature of the specific fact to which the sentence corresponds is independent of the attitudes and beliefs that individuals and groups have toward the fact in question. It is common to use the word 'stance' to refer to the beliefs and attitudes of individuals and groups, so using this terminology we may express the independence thesis by saying that for the discourse in question there is a stance-independent reality (realm of facts) that the discourse is about, and the facts comprising that reality are what make certain sentences of that discourse true.

Convergence: Ideally, use of the proper methods of inquiry (which may differ from discourse to discourse) may be expected to lead individuals (at least under suitably ideal conditions) to converge in a great many of their judgments about the subject matter of the discourse in question.

Discourse satisfying these four theses involves sentences that are (or may be) objectively true and hence we may say that the discourse itself is objective. Of course, it is possible for some realm of discourse to feature claims that **purport** to be objectively true but fail to be so because one or more of the above theses fail to hold in relation to the discourse in question – a possibility to which we shall return below.

Moral objectivism, then, at least as it is commonly understood by philosophers, is the view that all four theses hold in relation to moral discourse: not only does moral discourse purport to be objective, it satisfies the objectivity requirements in question and thus some moral judgments are objectively true. Sometimes this is put by saying that there is a single true morality. As we shall see, some philosophers have denied one or more of the four theses in relation to moral discourse and thus denied that morality is objective.

Determining whether moral objectivism is correct requires an examination of fundamental philosophical questions about the meaning, truth, and justification of moral judgments – questions central to that branch of ethics called 'meta-ethics.' But it also requires an examination of the very notion of objectivity. And here we find two models of objectivity. One of them is inspired by discourse about the physical world

(including ordinary nonscientific discourse about the world as well as scientific discourse) and which I will refer to as the model of ‘ontological objectivity’ – so called because the central idea is that there is an ontological realm of ‘really’ existing objects and properties that sentences from a particular discourse purport to be about and which serve to make true certain of those sentences. An alternate, more modest form of objectivity, which I will call ‘methodological objectivity,’ is less focused on matters of ontology and more focused on methods of reasoning that govern the discourse in question.

In what follows, we begin with a brief characterization of the ontological model of objectivity and then proceed in the next four sections to consider some of the evidence for and controversy about whether moral discourse is ontologically objective. After reviewing the pros and cons of the claim that moral discourse is ontologically objective, we turn to the second model of objectivity – a model that promises to make sense of objectivity without ontology.

Ontological Objectivity

In meta-ethical discussion over the objectivity of moral discourse, discourse about ordinary common-sense objects and their properties as well as scientific discourse – often referred to as descriptive discourse – is taken to be paradigmatic of objective discourse. Roughly, the idea is that descriptive discourse is (or at least purports to be) about a realm of objects and properties in certain combinations (facts) whose nature and existence is independent of our beliefs, conventions, attitudes, and other mental stances we might take toward those facts. Here, the emphasis is on considerations of ontology – on what exists – hence the label ‘ontological objectivity.’ Moreover, the ontological objectivist typically embraces a strong form of the independence thesis, viz.,

What makes some sentence true is that it corresponds to some sort of stance-independent fact – where the existence and nature of the fact in question is independent of the actual and ideal stances of individuals or groups.

The significance of this thesis of strong independence (SI) will emerge later on when we turn to methodological objectivity.

So the model of ontological objectivity (using descriptive discourse about objects and properties in the world as an example) clearly involves the first three objectivity theses: descriptive discourse serves to express beliefs (cognitivism), some of which are true (truth) when they correspond to

stance-independent facts (independence). Barring epistemological skepticism, we may also expect suitably motivated inquirers, using proper methods of inquiry, to converge in their beliefs about this realm of objective fact since their inquiries are being constrained by an objective, stance-independent reality.

Ontological Objectivity and Moral Discourse

Does moral discourse have the trappings of ontologically objective discourse? Indeed, is it a form of **descriptive** discourse – discourse about a special subject matter, but nevertheless a discourse that is properly interpreted as representing a realm of objective moral facts? Those who think so often point to a number of ‘markers’ – features that are deeply embedded in moral thought and discourse – that either reflect or at least seem to support the various objectivity theses. Let us consider some of them in more detail.

Grammatical and Semantic Markers

Perhaps the most obvious markers of objectivity concern matters of grammar and semantics.

O1: Moral sentences such as ‘John’s lying to Brenda was wrong,’ in which a moral term appears, are in the indicative mood and are used to make genuine assertions that express a (sincere) speaker’s beliefs.

O2: Moreover, because moral sentences are typically used to make assertions they are truth apt: they are candidates for semantic evaluation in terms of their truth and falsity. Sentences which predicate the truth or falsity of a moral sentence seem to make perfect sense (e.g., ‘It is true that John’s lying to Brenda is morally wrong,’ ‘It is false that contraception is morally wrong,’ and so on).

O3: Moreover, logically simple moral sentences (e.g., ‘It is wrong to steal’) can embed in all sorts of logically complex grammatical constructions, most notably truth-functional and quantificational constructions (e.g., ‘If it is wrong to steal, then it is wrong to encourage others to steal.’) It would seem that such logically complex sentences have truth values that are determined by the truth values of their simpler constituents.

Ontological Markers

The following two markers have to do with the ontological status of the subject matter of moral discourse.

O4: Moral terms that appear in moral sentences (e.g., 'good,' 'right,' 'virtuous,' and their opposites) seem to be used to denote properties that are (or may be) possessed by items of moral evaluation. For example, to say of an action that it is wrong appears to attribute the property of wrongness to the action. Furthermore, some moral sentences are used with the apparent intention of picking out moral properties and talking about them, as when one utters the sentence 'It was the badness of the practice of American slavery that eventually led to its abolishment.'

O5: Moral truth and moral error are genuine possibilities. When we disagree over some moral issue, we take ourselves to be engaged in a genuine dispute where not all parties to the dispute are correct in their moral convictions. What is apparently being assumed in such disagreements is that there is a fact of the matter about the issue in dispute – that there is an objective truth about the matter. This makes it natural to think that the truth (or falsity) of a moral sentence is a matter of its correspondence (or lack of correspondence) to some moral fact. The putative fact that an action is wrong (supposing it is) would seem to be what makes true a sentence expressing this fact. Moral error results when what one says or believes fails to properly record moral reality.

Epistemological Marker

Finally, the following marker has to do with matters of justification and knowledge.

O6: We dispute moral claims by offering reasons for their truth or falsity and thus take such claims as being susceptible to justification. One can be justified or unjustified in claiming that John's action was morally wrong depending on one's evidence for the claim – evidence that can be offered, disputed, and discussed with others. Moreover, in some cases we at least suppose that we have some moral knowledge. Surely we take ourselves to know that torturing puppies for fun is morally wrong. Since justification and knowledge in ethics (as elsewhere) seems to require that there be reliable methods of inquiry suitable to the form of inquiry, one would expect there to be a moral methodology that would enable inquirers using it to reach a high level of interpersonal convergence in moral belief.

Thus, moral discourse, at least at first glance, seems to possess all of the characteristic marks of objectivity – indeed ontological objectivity. Many philosophers go one step further and claim that moral discourse is genuinely ontologically objective

and that moral discourse is a kind of descriptive discourse whose primary function is to represent a realm of moral facts.

But ontological moral objectivism is controversial: we find a variety of meta-ethical positions that deny one or more of the four objectivist theses and among moral objectivists we find a variety of specific meta-ethical positions that differ over questions of semantics, metaphysics, and epistemology in relation to moral discourse. Let us now briefly survey some of these positions.

Moral Realism

One very straightforward way to accommodate O1–O6 is simply to affirm the four objectivist theses and, in particular, the idea that there is a realm of moral properties (and moral facts) that are strongly independent of our attitudes and beliefs about them and which serve as an objective basis for the truth and falsity of moral sentences. This meta-ethical position is known as moral realism and the task of this kind of realist view is to explain what sorts of fact serve as truth makers for moral judgments and how it is possible to have justified belief and perhaps knowledge of moral truths. Ontological naturalists, who are moral realists (Sturgeon, 1984; Railton, 1986, 1996; Boyd, 1988; Brink, 1989; Bloomfield, 2001), claim that moral properties and facts are identical to certain natural properties and facts – properties and facts that are the proper subject matter for empirical science to investigate. In the history of meta-ethical inquiry, we find various attempts by philosophers to 'reduce' moral properties and facts to some species of biological, psychological, or sociological fact. For instance, Spencer (1895) held that the property of being better than, which he took to be basic in ethics, could be reduced to the property of being more highly evolved. Ontological nonnaturalists in ethics (Moore, 1903; Ross, 1930; Shafer-Landau, 2003) hold that moral properties and facts are of a special nonnatural kind; that rightness, for example, is not identical to any natural property, but is nonetheless a real property.

Naturalist realists face the challenge of explaining why some specific set of natural properties and facts is identical to moral properties and facts. This in turn would seem to require a plausible semantic account of moral judgments that fits with naturalist realism, something which has proved difficult to do. Nonnaturalists, by contrast, propose to bloat our ontological commitments: in addition to being metaphysically committed to those entities in the natural

world that common sense and natural science commits us to, the nonnaturalist wants to add a realm of nonnatural properties and facts. Such metaphysical extravagance has been met with strong resistance from philosophers who think that such properties and facts are mysterious metaphysical accretions and that there are serious epistemological worries accompanying any such view.

Denying Ontological Objectivity in Moral Discourse

Some philosophers deny moral objectivism because they deny the thesis of cognitivism in relation to moral discourse. They claim that although the surface grammar strongly suggests that moral judgments express beliefs and thus are used to make truth-apt assertions, nevertheless all of this is misleading. Rather, according to the meta-ethical position known as noncognitivism (Stevenson, 1937, 1944; Ayer, 1946) and more recently as expressivism (Gibbard, 1990, 2003; Blackburn, 1993, 1998; Horgan and Timmons, 2006), moral judgments are not really in the business of expressing beliefs that purport to represent or describe moral facts; rather they instead function to express some noncognitive attitude toward the object of evaluation. Thus, for instance, according to emotivism (one kind of noncognitivism), uttering a sentence such as 'Abortion is wrong' really functions primarily to **express** one's negative feeling toward abortion and is roughly equivalent to saying, 'Abortion: boo!' So, the noncognitivist denies both the theses of cognitivism and truth (in relation to moral discourse) and hence denies the independence and convergence theses as well. What makes this view fairly radical is that it distinguishes between the surface trappings of moral discourse and its true, deep semantic working, and claims that a proper semantic interpretation of the discourse reveals that it really does not even **purport** to be objective, that, to repeat, moral sentences are not really used in thought and discourse to express beliefs capable of being true or false.

A slightly less radical view, the error theory (Mackie, 1977), maintains that although moral discourse is properly interpreted as at least purporting to be objective, its various objective pretensions result from massive error. More precisely, the error theorist accepts the thesis of cognitivism in relation to moral discourse, but denies the thesis of independence and so denies the claim that affirmative moral sentences are ever objectively true. This position is analogous to atheism. That is, an atheist holds that religious discourse involving affirmative claims about God or gods purports to be

objectively true, but, claims the atheist, there are no theological facts of the relevant sort that can make true affirmative claims about God or gods, and so no such claims are objectively true. The error theorist in ethics is saying something similar. The moral judgment 'repaying one's debts is morally right' purports to attribute the property of moral rightness to the activity of repaying debts, but since there are no such moral properties this sentence and all affirmative moral sentences (taken literally) are false.

Finally, versions of moral relativism (Harman, 1984; Wong, 1984) typically affirm the theses of cognitivism and truth, but maintain that moral truth is not independent of the attitudes of individuals and groups. Rather, for a typical relativist, what makes a moral claim true is that some group accepts some set of moral principles and these principles are the very standard (for that group) that determine (together with nonmoral facts) which further moral sentences are true. The idea is that the sentences expressing moral principles are counted as true in virtue of being accepted by some group and the more specific moral sentences that (together with nonmoral facts) follow from these principles express derivative moral truths. So, if some group accepts as a basic moral principle that eating meat is morally wrong, then the sentence 'Eating meat is wrong' is true – relative to their moral outlook. If some animal (or its remains) is as a matter of fact meat, then this fact together with the general moral principle in question implies specific moral truths about eating this or that animal or its remains. Now, if some other individual or group does not have any such principle against meat eating, or has a principle that requires eating meat, then the sentence 'Eating meat is wrong' is false – relative to their outlook. Thus, for the relativist, conflicting moral sentences may be equally true.

There is a variety of ways to develop this basic relativist idea, but all of them are committed to denying the idea that there is some realm of moral fact that is independent of the stances of individuals and groups; in short, for the moral relativist, there is no single true objective morality.

Noncognitivism, the error theory, and relativism have their able defenders, but of course embracing one of these positions means having to claim either that at least some of the various objectivist markers (O1–O6) are illusory – not really characteristic of the discourse – or that they are genuine but deeply error ridden. Such views strike many philosophers as meta-ethical options we should try to avoid in making sense of moral thought and discourse (Wright, 1992; Timmons, 1999).

Methodological Objectivism

In light of the metaphysical and epistemological problems that beset realist (ontological) accounts of moral objectivity, some philosophers are attracted to a different model of objectivity – a model that looks to the realm of mathematics and logic for a way of understanding how moral discourse can be objective even if there are no dedicated moral properties and facts (of the sort associated with ordinary descriptive discourse) that would serve as truth-makers for moral sentences. Such meta-ethical views are often called ‘constructivist.’ A central idea behind versions of moral constructivism, then, is that just as we need not suppose that there is a mystical realm of numbers and mathematical relations that make certain mathematical sentences true, so we need not make any heavy-duty ontological assumptions in making sense of the apparent objectivity of moral discourse (Putnam, 2004). For both sorts of discourse – mathematical and moral – so long as there are **methods** of reasoning governing these types of discourse that would lead properly motivated individuals to converge in their views on a large enough number of claims within those areas, then we have a proper basis for affirming the objective pretensions of both realms. So, in contrast to the ontological model of objectivity that emphasizes an SI thesis, the present model takes the thesis of convergence as central to moral objectivity. Let us explore this model in a bit more detail.

Suppose, then, that associated with moral discourse is a method of moral thought and reasoning that would (if properly applied) ideally lead to interpersonal convergence over a wide range of moral issues; in other words, suppose the convergence thesis holds for moral discourse. Then, according to this line of thought about objectivity, we would have the materials to vindicate the other objectivity theses – cognitivism, truth, and a modest form of independence. How might this view be developed?

The general constructivist idea is that there are better and worse methods of moral thinking – methods that involve constraints on moral deliberators and on the circumstances in which they deliberate. For instance, according to one variety of constructivism, called the ‘ideal observer’ theory (Firth, 1952; Carson, 1984), the proper method of moral thinking requires that moral deliberators thinking about a certain moral issue must for example have certain intellectual virtues and sufficient knowledge of non-moral facts to be in a position to arrive at moral verdicts that have the status of being true. But what is crucial to the ideal observer view and constructivist

views generally is that it is the attitudes of ideal observers that constitute or make true certain moral judgments. So, although the constructivist accepts the independence thesis (in addition to cognitivism, truth, and convergence), she embraces the following modest form of this thesis in contrast to the strong form embraced by the ontological objectivist:

Although the truth of a moral sentence is independent of the stances of actual individuals and groups, moral truth is ultimately constituted by the stances of ideal individuals or groups – call them ‘ideal stances.’

Granted, some moral constructivists introduce ontological talk of moral properties and facts at this point (Rawls, 1980; Scanlon, 1998), understanding such properties and facts to be ‘constructions’ grounded in facts about moral convergence. But a moral constructivist need not make these ontological claims; she can rest content in emphasizing the importance of there being a method of moral inquiry that would lead all or most ideal agents (agents who are engaged in moral thinking under ideal circumstances) to converge in a great many of their moral convictions (Smith, 1994). What the constructivist hopes to do, then, is develop a meta-ethical view that satisfies the four main objectivist theses without (apparently) having to embrace heavy-duty ontological assumptions, and thereby vindicate the objectivity of moral discourse. In short: moral objectivity without (moral) ontology.

Of course, any constructivist view carries the burden of spelling out a moral methodology or process of moral reasoning that would lead ideal moral inquirers to converge in their moral views. The task of doing so poses a seeming dilemma for the moral constructivist (Timmons, 2004). On the one hand, if the favored moral methodology that is to be a basis for moral truth is characterized in morally neutral terms, then the constraints on such reasoning will be insufficient to lead those following the method to reach the level of convergence in their moral verdicts that a vindication of objectivism requires. This would mean, according to the constructivist, that there is no objective moral truth about those moral matters regarding which moral methodology fails to yield convergence under ideal conditions. Hence, the view would be committed to a kind of moral error theory – there is no fact of the matter in relation to a great many moral issues, contrary to what we suppose. On the other hand, if, in order to make the moral methodology yield substantive moral verdicts, one characterizes the methodology making use of moral assumptions, then relative to one set of

moral assumptions the method will yield one set of moral 'truths,' but relative to a competing set of moral assumptions the method will yield a different and perhaps conflicting set of moral 'truths.' But this commits the constructivist to moral relativism, which, as we have seen, is at odds with the idea that moral discourse is objective – that with respect to a large number of moral issues there is a single truth of the matter. Avoiding the error theory and relativism and thereby preserving objectivity is thus the main challenge for the moral constructivist.

Conclusion

The issue of moral objectivity, involving, as we have seen, semantic, metaphysical, and epistemological issues, is the central topic of meta-ethics. About the objectivity of moral discourse there are two questions to be distinguished. First, what sorts of objective features or markers are genuinely possessed by moral discourse? Second, assuming that moral discourse does genuinely possess such markers, how should they be interpreted? In particular, do they require, for their vindication, some version of moral objectivism? In response to these questions, we have surveyed a number of currently debated meta-ethical options, including two conceptions of objectivity.

Objects, Properties, and Functions

R J Stainton, University of Western Ontario, London, Ontario, Canada

One of the most fundamental metaphysical distinctions is that between objects and properties. Given its depth and importance, it's perhaps unsurprising that though the distinction can be given in a canonical form, it also admits of some puzzling complexities.

By way of a first pass, let's consider some examples of objects and of properties and try to extract some hallmarks – linguistic and otherwise – of each. Examples of objects include my cat, you, the tree outside my window, and the planet Earth. These four are all physical objects. There are mental objects as well – which, depending upon whether the mental reduces to the physical, may or may not be a subvariety of physical objects. Mental objects include my wish to write a book, the pain I felt just now, my dream last night. So much for examples. Some hallmarks of objects include that they are individual things, which things (at least in the simple cases) have a specific location in space and time. What's more, objects can be counted. And, in counting, one can always ask: Is this object the same individual as that one, so that it should be counted just once, or are there two individuals here? (E.g., if Samuel Clemens is the same person as Mark Twain, then when Clemens is alone in the room, there aren't two individual people there: Clemens *and* Twain. But if Bill Clinton and Tony Blair are the sole people in the room, two people are therein.)

Examples of properties – also called 'attributes,' or "qualities" – include being red, being from Canada, being painful, knowing Charles Darwin personally, weighing exactly 16 trillion kilograms, and having belonged to Abe Lincoln. Hallmarks of properties include *not* being individual but rather being general, and being located not in one place but at various locations at once or at none. Thus the property of being from Canada is instantiated in many objects, in many places; and it might be that the property of knowing Charles Darwin personally is instantiated by no object at all these days. As for counting, while one can count *instantiations* of being red – i.e., count how many red objects there are – it doesn't really make sense to count being red itself. Another hallmark of properties, as opposed to objects, is that a given property typically has contrary or opposite properties. For instance, being green is contrary to being red, being from Spain is contrary to being from Canada, being pleasurable is contrary

to being painful. (Contrast objects: What is the contrary of Abe Lincoln? What object do you get when you negate *him*? Or, again, what do you get when you negate my window? These questions don't even seem to make sense.)

There are also *linguistic* hallmarks of the object-versus-property divide. The linguistic correlates of objects are proper names ('Rob'), noun phrases ('the planet Earth'), pronouns ('me,' 'he,' 'she,' 'it'), and demonstratives (like 'this' and 'that'). The linguistic correlates of properties, by contrast, are adjectives ('red'), verb phrases ('weighs 16 trillion kilograms,' 'is from Canada') and, as above, gerundives ('belonging to me'). (In formal logic, the divide corresponds to that between constants and variables [often symbolized by lowercase letters from the beginning of the alphabet for constants, and lowercase letters from the end of the alphabet for variables: constant *a* or variable *x*] on the one hand and predicates [often symbolized by capital letters from the middle of the alphabet: F, G] on the other.) Another linguistic hallmark is this. If, following Peter Strawson (1971), we think about the different actions typically performed in speaking a sentence – for instance in saying "That cat weighs 18 pounds" – we may note that "That cat" is used for one kind of job, while "weighs 18 pounds" is used for a quite different job. "That cat" is used to *refer to*, or *talk about*, the cat. In contrast, "weighs 18 pounds" is used to *attribute* something of the cat, to *say of* it that it weighs 18 pounds. A final linguistic hallmark, then, is that in speaking, we refer to objects, but we attribute properties.

So much for the first pass at objects versus properties. The divide gets muddy, however, when we leave the canonical examples. That's because there are things that are objectlike in some respects but propertylike in others. These hard-case objects come in at least two varieties: *abstracta*, like numbers, and *kinds*, such as gold and horse. One obvious problem with such objects concerns their location. Being abstract, the square root of seven doesn't seem to have any location. The same holds for kinds: gold has multiple locations. Moreover, there are contraries to gold: silver, uranium, etc. Yet abstracta and kinds are objectlike as well. Gold *has* certain properties: it boils at 2966 °C and melts at 1063 °C. So, it isn't itself a property. And gold, along with the square root of seven, is denoted by a name; and, in speech, such things are referred to, not attributed. So, kinds and abstracta seem to exhibit some of the hallmarks of objects and some of the hallmarks of properties. At bottom, the difficulty is that such objects have instances, rather than merely being instances.

To take another case, consider the novel *War and Peace*. Some will say that it's another abstract object: it itself has no location, though its instances (i.e., copies of the book) do. But one could also take *War and Peace* to be like gold, which is located in many places at once. Whichever way one goes, it too has instances, rather than merely being an instance; and so it does not have one unique location. See **Figure 1** for a summary.

One last hard case. It seems that we can form names and descriptions associated with properties. Thus, consider 'the property of being red.' This description has all the linguistic hallmarks of an object, in terms of both its form and the job it is used for. More than that, it has some of the nonlinguistic hallmarks too. We can ask whether what 'the property of being red' stands for is identical to what 'the property of being green' stands for. (Obviously the answer is no.) We can count such things. And so on. What one typically says is that 'the property of being red,' 'that property,' 'my favorite color,' and so on stand for objects that are associated with properties but do not themselves stand for properties. (Of course, this leads to the odd result that 'The property of being red is not a property' is not actually false, since according to the view under consideration, the first five words of this sentence *stand for an object*, so the sentence says of this object that it's a property – which it isn't! See Frege 1891, 1892 for a detailed discussion.)

One could continue pursuing such complexities at enormous length. For present purposes, it's enough to notice that there seem to be various kinds of objects. And several of them are propertylike in certain respects. It is in part because of the diversity of objects, and their affinities to properties, that it's hard ultimately to distinguish objects from properties.

In light of these complexities, one might wonder: Why are properties required at all? Why not just have yet another variety of object – namely, those objects that don't merely have instances (as with kinds and

abstracta) but that can actually apply to other objects? Indeed, why not have the world be exhausted by its objects? Thus, on this suggestion, being from Canada would simply *be* a fourth kind of object beyond instances, kinds, and abstracta. In response, I want to give one reason that one seemingly cannot do away with the object/property distinction altogether, reducing everything to objects. It's a reason that goes back to Antiquity, and it has to do with combining in predication.

Patently, some objects can't combine predicationally at all: Rob and the tree can't be fused together into a complex fact. At best they can be combined by smashing them together or putting one inside the other or some such. But, so the 'properties are objects' idea goes, there are some objects that can combine in predication; there are certain objects that apply to others. Take Rob Stainton and being Canadian, understood, as per the proposal, as two different kinds of objects. These 'objects' combine together, in predication, in the sense that the former exhibits the latter: I am Canadian. The difficulty, however, is this: Not all objects actually so combine, even when one of them is of the supposed 'applying kind.' For instance, Rob Stainton doesn't in fact combine with being Algerian, and George Bush doesn't combine with being Canadian. So, what holds the two types of supposed objects together when the 'applying object' really does combine with the instance one? A natural thought is that the relation 'exhibiting' puts together the objects that really go together, and not the others: 'exhibiting' fuses Rob with being from Canada, but it does not fuse Rob with being from Algeria. However, if *all* things are objects, then relations – including 'exhibiting' – are objects too. And if, as we've been seeing, objects need something to put them together to distinguish those where the combination does really happen from those where it doesn't, 'exhibiting' needs something to put *it* together with – e.g., Rob and being Canadian. What, then, puts together these three objects in predication such that it doesn't fuse 'exhibiting,' Rob and being Algerian? We are faced with a choice: either there is something that is not an object and that puts objects together in predication, so that not everything is an object, or there is an infinite regress. Since the latter is absurd, we conclude that some things aren't objects. In particular, properties are non-objects, in the sense that they go together with objects in a way that two objects cannot: nothing is required to 'fuse' an object with a property. That, it is often said, is why we need some kind of object/property divide, even if it is hard to lay out.

Figure 1 Varieties of objects.

An interesting upshot, of course, is that not all that is, is an object. Even more interesting, if anything we can refer to is an object, then if properties are not objects, we simply cannot refer to them. We can't talk about them, no matter how hard we try. At best we can refer to their associated surrogates, as in the previous example of 'the property of being red' – which surrogates are objects, not actually properties.

Let's turn now to the relationship between properties and functions. What I hope to explain is how properties are, in a certain sense, equivalent to a peculiar kind of function: namely, a function whose output is a truth value. (See Frege 1879, 1891, 1892.) Now, mathematical functions are familiar: they take numerical inputs and yield numerical outputs. For instance, (1) is a function that takes zero as input and yields four as output, and takes one and yields nine as output, and so on.

$$(1) y = (x + 2)^2$$

But the notion of function can be generalized so that the inputs are not just numbers but objects of all kinds. To understand the broadening of the inputs, consider (2), which is a function that takes an individual as input and yields his or her father as output.

$$(2) y = \text{the father of } x$$

If you take me as input, the output is Keith Stainton. One could also have a function whose input was a country and whose output was the language most widely spoken in that country. If Canada were taken as input, this function would output English. It should be clear that for any kind of object, we can cook up a function into which it can be input: trees, windows, universities, etc.

So, inputs to functions can be generalized. Moreover, their outputs needn't be numbers, either. Consider, in particular, a function whose output is either TRUE or FALSE (or yes/no, or 1/0, or any other pair of binary values). Specifically, consider a function that outputs TRUE if the object input meets the condition specified and that outputs FALSE if it doesn't. For instance, consider the function such that its output is TRUE if x is from Canada and its output is FALSE otherwise. This is the key point: such functions are interchangeable with the properties. To the property of being from Canada, there corresponds f , the function from objects to truth values, such that f outputs TRUE when the object is from Canada and outputs FALSE otherwise. (Gottlob Frege called

such peculiar functions 'concepts'; Bertrand Russell called them propositional functions.)

We saw above that objects and properties have different linguistic correlates. Given that propositional functions are interchangeable with properties, it is unsurprising that a similar point applies to them. Specifically, the correlate of a verb phrase or an adjective will be a function from an object to a truth value. (In terms of Montague grammar, the correlate of objects will be expressions of semantic type $\langle e \rangle$, while the correlate of (first-order) functions will be expressions of semantic type $\langle e, t \rangle$.) And, as before, puzzles arise about whether functions are really so different from objects. At first the distinction is clear: objects are the inputs and outputs, while functions operate on them. But it seems that we can objectify functions and talk about them. This I did above: I talked about the function from things that are from Canada to TRUE. Put another way, there are functions whose inputs are functions, and functions whose outputs are functions. What's more, there are alleged objects, such as the kind gold, that seem to be true of instances; hence, they could be taken to be a propositional function, rather than as objects. But then are they just another kind of object? The answer here, again, is that there can't only be objects: we'd need something to combine 'ordinary objects' with 'function objects' that wasn't itself of either kind, or we'd have a regress. What goes for properties goes for propositional functions: there may be various kinds of objects, some of which exhibit functionlike characteristics, but we cannot do away with genuine functions altogether.

Ordinary Language Philosophy

P Snowdon, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

‘Ordinary language philosophy’ is the name given to some conceptions of philosophy, which emanated, after the Second World War, from J. L. Austin in Oxford and from Wittgenstein in Cambridge, and which championed the importance for philosophy of attention to ordinary language. The name itself, the origin of which is not recorded, has perhaps been more used by opponents of these ideas than their friends and so has, to some extent, become a term of mild abuse.

Language and Philosophy

Language itself has always been of interest to philosophers. Our ability to understand and use language is such an obvious feature of our cognitive capacities that any attempt to describe and explain cognition must consider language. In the early modern period such philosophers as Locke and Berkeley provided theories of the nature of language, trying to account principally for its semantic properties. Their thinking, however, was dominated by a belief in the priority of thought, conducted according to them in a prelinguistic medium of ideas, over language. Language was regarded as a medium for public expression of private thoughts, and its interpretation was viewed as making words public ‘signs for’ private ideas. For them the problem, which generated considerable disagreement, was whether the seemingly manifest differences between different parts of language, between, say, names and adjectives, required the postulation of different sorts of ideas. This was, of course, a concern about the nature of ordinary language. By the beginning of the 20th century, a more comprehensive philosophical engagement with the nature of language emerged in the writings of Frege, Wittgenstein, and Russell. This engagement was inspired by the emergence of formal logic, with its semantic categories, and it was not driven by any prior commitment to the priority of thought over language. There was a real concern with a wide range of different constructions in ordinary language. Thus began what became a, perhaps the, central branch of philosophy, the philosophy of language. Of course, this concern with language was a concern with ordinary language, amongst other sorts of language.

Ordinary Language Philosophy

The name ‘ordinary language philosophy’ does not stand for this general theoretical concern in

philosophy with the nature of ordinary language or for any particular theory about ordinary language. Rather, it stands for two linked approaches to, or theories about *philosophy* itself. The approaches shared the conviction that the key to, or at least a necessary condition for, finally solving philosophical problems lies in some sort of detailed attention to ordinary language. This common theme led philosophers at the time to think that there was a single movement, representing a revolutionary approach to philosophy, which held out hope of laying recalcitrant philosophical problems to rest. However, as we shall see, it is an illusion to think there is a common movement here.

The Oxford Version: Austin

The Oxford ordinary language movement was led by, or inspired by, J. L. Austin, who became White’s Professor of Moral Philosophy at Oxford in 1956. Austin himself did not publish much during his lifetime, but established his leadership within a group of highly talented philosophers in Oxford, including Grice, Strawson, Urmson, and Warnock, partly due to his seniority, but also to his extraordinary critical intelligence and personality. Austin had a deep interest in language and wrote about what he called performative utterances, that is utterances such as saying, in the right circumstances, ‘I name this ship *Victory*,’ whereby the act of speech itself accomplishes what it ascribes, in this case conferring a name on a ship. He developed a more general theory of the acts we perform by speech in the William James Lectures he gave at Harvard in 1955, published under the title *How to do things with words*. In these he criticizes his earlier views on performatives and then introduces the famous distinction between locutionary, illocutionary, and perlocutionary acts, which are categories for different types of acts we do in or by using language. Austin also presented his own theory of truth. These publications contain Austin’s theories of language and of some of its properties.

Austin, however, thought that, in general, the right method when doing philosophy is to “proceed from ordinary language, that is, by examining *what we should say when*, and so why and what we should mean by it” (Austin, 1961: 129). In the most systematic presentation of his views, in his article ‘A plea for excuses,’ Austin recommended this for three reasons. The first is that philosophers need to ensure their own language is clear; the second is that we need to prize words apart from the world so that we can look at the world without blinkers; finally, ordinary language

contains many distinctions and subtleties that have withstood the tests of time and so must represent a subtle and plausible way of thinking about things, particularly things in normal life. Austin added that his view is that ordinary language will be the 'first word' when doing philosophy, though it need not be the 'last word.' He recommended that one should regularly consult a dictionary to get the sense of the categories and words related to a certain area or domain. Austin himself spent considerable effort plotting the distinctions that ordinary language categories embody. For example, what is the difference between a tool and a utensil? What is the difference between doing something willingly and voluntarily? Questions such as these were studied in Austin's famous Saturday morning discussion group in Oxford. It is indeed a reasonable conjecture that one thing that appealed to Austin about pursuing such questions is that they can be answered by cooperation within a group, amongst whom agreement can be reached, in sharp contrast to what has traditionally been the very solitary methods of philosophy with its continual disagreements.

Some Questions about Austin's Approach

There is, surely, no doubt that plotting the incredibly subtle distinctions of ordinary language is of interest in itself, and it certainly fascinated Austin. The main question that arises, of course, is what is its relation to, or value for, philosophy. The questions of philosophy are characteristically highly general, such questions as 'Is the will free?', and 'Do we know about the external world?' How, then, does a study of the subtle and rather specific categories of ordinary language help with them? The major weakness of Oxford-style ordinary language philosophy is that it is not based on any theory of the nature of philosophical questions that explains and justifies the relevance of a study of ordinary distinctions to it. In fact, it would have been somewhat anathema to the mind set of such ordinary language philosophers to have a general theory of philosophy, but it meant that its relevance remained obscure.

When Austin discussed philosophy head on, as he did in *Sense and sensibilia*, criticising the sense datum approach of Ayer, he noted that philosophers employ expressions in a way which does not fit their ordinary use. For example, he pointed out that the central terms 'direct perception' which often figure in the very formulation of the problem are used in a special way (see Austin, 1962: 14–19). It is a mistake though to take this discrepancy as a basis for criticism of the talk by the philosophers. It merely reveals that the philosopher's use is technical and in need of an

explanation. Austin also clearly thought that the categories of philosophers are far more general than those which are of normal employment. But, again, this fact, in itself, does not amount to a criticism of those general categories.

If this assessment of the gap at the core of Austin's approach is correct, it explains why the approach, despite the fascinations of its ordinary language investigations, simply withered in its appeal to those engaged by philosophical questions. A crucial moment was the publication in 1959 of Strawson's *Individuals*, with its self-avowed aim of doing highly general metaphysics.

The Cambridge Version: Wittgenstein

The second attitude to philosophy that was called 'ordinary language philosophy' is that of the later Wittgenstein, during his period after 1929 when he was primarily at Cambridge. The major presentation of the approach is in *Philosophical investigations*, published in 1953 after Wittgenstein's death in 1951. In the evolution of his later philosophy Wittgenstein was, in part, attempting to explain why his earlier, highly abstract and metaphysical philosophy, contained in the *Tractatus*, is wrong. In that earlier work, Wittgenstein attempted to describe the essential nature of contingent propositions, and the states of affairs that they report, basically by picturing the elements. There are also the tautologies of logic and mathematics. The pronouncements of philosophy itself seem not to belong to either category, and so the contents of the *Tractatus* were themselves inexpressible by its own standards. Philosophy itself was, therefore, a process you went through in order to realize you had to leave it behind. It is, as Wittgenstein put it, like a ladder you climb only to throw away, no longer needing it. In the process, though, something profound is shown, although not said. This is a highly unusual and paradoxical conception of philosophy.

In the later period Wittgenstein rejected his earlier ideas about the essence of saying, holding instead that speech and understanding are parts of human life, which may take many forms (as Wittgenstein might have said, 'We play many language games'), and which have no hidden common essence that a reflective process like philosophy can discern. However, he retained even in the later period an attitude to what philosophy is that is unusual and paradoxical. His theory is that there are what we might call two activities, which go under the name 'philosophy.' There is, first, traditional philosophy, which for Wittgenstein was often taken to be the *Tractatus*, according to which there are supposed to be distinctively

philosophical problems, concerned with the essence of things and our knowledge of the world, and theories are proposed as answers to these questions and rationally assessed. According to the later Wittgenstein, traditional philosophy is not actually engaging with real problems. They are, rather, pseudo problems. He suggested that engagement in traditional philosophy always stems from an initial mistake when one speaks, employing the words of ordinary speech, in a way which is not actually in accordance with how the term in question is really used. They start, that is, from linguistic mistakes. Wittgenstein's view is that these mistakes are not random, but stem from properties of the language we employ. For example, the fact that I can say both I have a pain in my foot and I have a bone in my foot may lead us to imagine that pains are special objects located in space in the same way as bones. He said, "A picture held us captive. And we could not get outside it, for it lay in our language and language seemed to repeat it to us inexorably" (Wittgenstein, 1963: sec. 115). Wittgenstein likened being misled to being tricked. "The decisive moment of the conjuring trick has been made, and it was the very one that we thought quite innocent" (Wittgenstein, 1963: sec. 308). This is a schematic characterization of what is, in many ways, itself a schematic conception of traditional philosophy.

What we might call real philosophy should, according to Wittgenstein, consist in doing what is necessary to remove the impulse to engage in pseudo theorizing. As he famously said; "What is your aim on philosophy? – To show the fly the way out of the fly bottle" (Wittgenstein, 1963: sec. 309). How is this to be done? Wittgenstein had a negative and a positive claim to make. The negative theme is that the impulse is not removed by offering a positive and novel theory about anything that philosophers have attempted to theorize about. That would be to engage in pseudo theorizing itself. The task, rather, is to remove the impulse, and it should be viewed as akin to exterminating a disease. "The philosopher's treatment of a question is like the treatment of an illness" (Wittgenstein, 1963: sec. 255). So the real philosopher should produce something like a pill which removes a headache. It is this idea that is meant when Wittgensteinians talk of philosophy as therapy. The positive recommendation is that the pill should be a reminder how language is actually used. "What we do is to bring back words from their metaphysical to their everyday use" (Wittgenstein, 1963: sec. 116). He added that "when I talk of language ... I must speak the language of every day" (Wittgenstein, 1963: sec. 120). Hence, the idea is that proper philosophy consists in reminding those in the grip of traditional

philosophy how we ordinarily speak. This, then, is the idea of Wittgensteinian ordinary language philosophy.

Some Questions About Wittgenstein's Approach

Of the many questions that Wittgenstein's later conception of philosophy prompts, I shall restrict myself to two. Does Wittgenstein's own practice actually fit it? It is fair to say that Wittgenstein is, in his later period, primarily a negative thinker, his primary aim being to show what is wrong with standard philosophical ideas about, for example, understanding, following rules, sensations, action, and necessity. However, he did not think that simply reminding people of what they say accomplishes such criticisms. Rather, his practice was to think himself into the views in a highly creative way to the point where it becomes clear that they represent illusions, but where it is also revealed why they might seem attractive. It is therefore highly misleading to summarize Wittgenstein's own practice as reducing to reminders of what ordinary people say. Second, although Wittgenstein officially seems to think that proper philosophy does not propose theories or add to understanding, he clearly advances theories or semi-theories himself. Thus, he positively links meaning and use (see Wittgenstein 1963: sec. 43), and he is often taken to be arguing for the clearly philosophical proposition that a private language is impossible (see for example, Wittgenstein, 1963: secs. 258–279). It is, therefore, colossally misleading to think that describing Wittgenstein as an ordinary language philosopher captures his real approach to philosophy.

The second question is whether there is any reason to accept Wittgenstein's official account of the nature of philosophy. There is no *a priori* demonstration by Wittgenstein that the massive variety of questions that traditional philosophers have grappled with are all pseudo problems, grounded at some point in a misuse of ordinary language. Indeed, that seems a remarkably implausible thought. To take an example, traditional philosophers often debated what it is to understand a word. Wittgenstein brilliantly criticized the most popular answer, but it does not follow that the question is misconceived and does not merit a theoretical answer. Moreover, Wittgenstein was, as we have seen, moved to indicate his own answer in terms of use and practice. It seems to me, therefore, that we should regard the attitude to philosophy in the later Wittgenstein as simply an ungrounded and independent commitment within his thought, which does not even fit his own practice.

Conclusion

Austin's own theories about language and knowledge and his critical discussions of the philosophy of perception have remained influential, but both the rhetoric about the centrality to philosophy of ordinary language and the practice of attending to it for the reasons that Austin gives have vanished. Wittgenstein's approach to philosophy is still accepted by some people, but for most the real interest of the later Wittgenstein lies in his discussions of such central concepts as understanding, meaning, rule following, privacy of experience, and so on, and not in his extreme attitude to philosophy.

However, the emphasis on attending to ordinary language lead to significant advances in the theory of language. When philosophers recommended studying ordinary language, they usually meant, or at least said, that it was to be done by asking whether we would or would not say a certain thing in a certain circumstance. So determining the verdict of ordinary language meant determining what would be said. The philosophical relevance of this was supposed to consist in its showing that a philosophical theory which affirmed that P is actually true in circumstance C, would be wrong if we would not say that P in those circumstances. This prompted Grice, who had been part of the circle around Austin, to reflect on the relation between what is true and what we would say. He noted that truth alone is not usually sufficient to lead to speech, but rather, speech is governed by principles, such as 'Be helpful' or 'Be informative.' He explained in terms of this theory how the saying of something can carry an implication that in no way corresponds to what the remark literally entails. For example, if I remark 'The Provost is sober today' my doing so carries the implication that he is normally not sober. Whether Grice's theory is correct is still under discussion, but the contrast between speech

and truth, which is damaging to the rhetoric of 'ordinary language philosophy,' has now become conventional wisdom in philosophy. This insight probably emerged when it did because of those tendencies known as 'ordinary language philosophy.'

Origin of Language Debate

C Neis, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Preliminaries

The origin of language belongs to the most prominent topics of linguistic discussions in the 18th century. There is no doubt that the debate on the origin of language peaked during a time of much attention to the

question of human faculties in general and to the investigation of the natural endowment of man in order to distinguish him from the realm of beasts or to promote man's emancipation from ecclesiastical dogma.

Of course, it was not only in the 18th century that the question of language origins became a subject of philosophical concern. Given the philosophical and anthropological relevance of the topic, it has always attracted the curiosity of scholars. Glottogonic tales of ancient times have influenced the development of

philosophical thinking on the origin of language. One of the best-known myths is the story of the Egyptian King Psammetichus I (died 610 B.C.), who wanted to find out which language was the oldest and ordered an experiment that involved two children to be raised in isolation. In the course of history, several sovereigns are said to have followed the example set by the Psammetichus experiment: King Frederick II the Stauffer (1192/1193–1150), the Scottish King James IV (1473–1515), and the Indian Mogul Akbar the Great (1542/1556?–1605).

Important benchmarks in the discussion of the origin of language are the foundational texts of Western culture: the Bible and the philosophy of ancient Greece.

In the Bible, there are two myths of crucial importance to the further development of the question: Adam's naming of the beasts and the following dialogue between Eve and the serpent, and the legend of the Tower of Babel which ascribes the emergence of the diversity of languages to an act of divine punishment. God vindicates his realm against the sinful attempt of Man to erect a tower reaching the sky by transforming the only language that united man until that time into an inconceivable variety of idioms.

These biblical legends raised the question of whether at the very beginning there was only one language (monogenetical hypothesis) or whether diversity reigned since language came into being.

Discussions on the Origin of Language in Classical Antiquity

In his dialogue *Cratylus*, Plato (428/427–349/8) (see Figure 1) offered important insights into the relationship between words and things (cf. Schmitter, 1987). The disputants Cratylus and Hermogenes tried to find out whether words are created by nature or made up by convention. Cratylus advocated the

Figure 1 Plato. Drawn by Klaus Froese.

natural origin of words, which was mainly based on principles of sound symbolism and imitation. The conventional origin of language was defended by Hermogenes, whose argumentation was essentially focused on the undeniable diversity of languages which seemed a suitable proof of the non-natural origin of words. A final solution to the question of the natural versus conventional origin of words was offered by Socrates (470/469–399), who was introduced as a mediator by Plato. Socrates was eager to show the complementary character of the two respective approaches.

The conventionalist approach had a deep impact on Aristotle's (384/383–322) conception of the relation between words and things. For Aristotle, this relationship was not granted by nature, but depended entirely on convention. It was by human consent, by convention, that an arbitrary relationship between words and things was established ("*non natura, sed ad placitum*").

An important contribution to the development of the discussion on language origins especially in the Enlightenment is the Epicurean conception. Epicurus (342–271 B.C.) gave his account of the origin of language in a letter to Herodotus in which he attributed the emergence of language to a natural necessity, thus rejecting the idea of a conventional language origin. Epicurean philosophy was made accessible to the Roman world by Titus Lucretius Carus (98–55 B.C.) who explained the origin of language in his *De rerum natura* as a result of the natural endowment of man. It was his own nature that forced man to utter the first sounds, and his elementary needs urged him to express his first vocalizations (*At varios linguae sonitus natura subegit mittere, et utilitas expressit nomina rerum*; Lucretius V: 1028–1029). For Lucretius, language was neither a divine gift nor the invention of an ingenious language-inventor, but the result of the physical predisposition of man who tried to express his desires in a way quite similar to animal communication.

Discussions on the Origin of Language in the Enlightenment

The Epicurean philosophy had a strong impact on the Enlightenment debate on the origin of language (cf. Gensini, 1999) and inspired particularly the thought of leading figures of French sensationalism such as Étienne-Bonnot de Condillac (1714–1780) (see Figure 2), Jean-Jacques Rousseau (1712–1778) (see Figure 3) or Julien Offray de La Mettrie (1709–1751). It is well-known that both Condillac and Rousseau heavily influenced the discussion of the origin of language which reached its climax in

Figure 2 Condillac. Drawn by Klaus Froese.

Figure 3 Rousseau. Drawn by Klaus Froese.

Figure 5 Locke. Drawn by Klaus Froese.

the origin of language competition announced by the Berlin Academy for 1771 (cf. Aarsleff, 1974).

The origin of language discussion had already been decisively influenced in the 17th century by René Descartes' (1596–1650) (see **Figure 4**) account of the nature of mankind in comparison to animals in his *Discours de la méthode* (1637). For Descartes, the faculty of language was the distinctive criterion of the human species in contrast to the animal world, permitting man to maintain a position of absolute supremacy. The faculty of language was conceived by Descartes as an indicator of the existence of human understanding and the soul, in sharp contrast to the instinctive mechanisms of animals.

Descartes' position had provoked the critique of Condillac, who conceived only a gradual difference between humans and animals, thus undermining the Cartesian idea of an unbridgeable gap between men and beasts. Condillac's most influential work for the origin of language debate was his *Essai sur l'origine des connaissances humaines* (1746), in which he presented a post-diluvial view of the origin of language integrated into an epistemological framework, tracing

the genesis of the operations of the mind. The epistemological framework underlying Condillac's *Essai* was largely influenced by John Locke's (1632–1704) (see **Figure 5**) *Essay concerning Human Understanding* (1690), but Condillac aimed at the abolition of the Lockean dualism between sensation and reflection for the benefit of the introduction of a leading rôle of sensation as the only source of knowledge (cf. Ricken, 1984).

For his explanation of language origins, Condillac imagined a couple of infants of both sexes, living isolated in a desert just after the great flood. Tracing their first steps toward the invention of language, Condillac described a kind of natural state, anterior to the civilized world, in which his hypothetical subjects lived in bestial conditions.

Condillac's conception of the origin of language was mainly focused on a generative reconstruction of the human mind, thus emphasizing the relation between language and knowledge. In contrast to Condillac, Rousseau, in his *Discours sur l'origine et les fondements de l'inégalité parmi les hommes* (1755), aimed at a generative reconstruction of human society.

According to Rousseau, the development of human society played a decisive rôle in the formation of language, but he was unable to cope with the difficult question of the anteriority of language or society, thus entangling himself in a vicious circle and leaving to others the solution of the problem (cf. Starobinski, 1971; Droixhe/Haßler, 1989; Neis, 2003).

Rousseau integrated his theory of language into his conception of a natural state of mankind, prior to the formation of civilization. For his account of the state of nature, Rousseau followed the ideas traced by the 17th-century natural law theorists such as Thomas Hobbes (1588–1679) (see Figure 6), Hugo Grotius (1583–1645), and Samuel Pufendorf (1632–1694). However, Rousseau rejected Hobbes' vision of the state of nature as a condition of permanent war by introducing his natural man (*homme de la nature*) as a creature who led a vagabond life and lived in harmony with his environment. Into his hypothetical initial state of mankind, Rousseau integrated his conception of the origin of language and made language arise as a result of the primitive needs of man. Following this Epicurean vision, Rousseau also adopted Condillac's theory of the *langage d'action*, a first step of communication based on gestures and instinctive cries (cf. Haßler, 1984).

The vision of society and language offered by Rousseau in the *Discours* had a strong impact on the discussion of the origin of language in the second half of the 18th century, especially on the prize contest on the origin of language organized by the Berlin Academy in 1769 (cf. Megill, 1974). After a long internal discussion, the Academy invited scholars from across Europe to submit their essays on the origin of language. As language was considered an essential component of the natural constitution of man, it was required to reveal how man might have invented it and whether he might have been able to create it on his own.

This question has also to be seen in the light of a discussion at the Berlin Academy which was caused by a lecture given in 1756 by Johann Peter Süßmilch (1707–1767): the *Versuch eines Beweises, daß die erste Sprache ihren Ursprung nicht vom Menschen, sondern allein vom Schöpfer erhalten habe*. In this text, Süßmilch, himself a member of the Berlin Academy, defended the divine origin of language and protested against all conceptions of the origin of language based on the Epicurean doctrine. Because of its high degree of perfection, language could only have been the work of God. Primordial man, lacking the higher dispositions of the understanding, would never have been capable of inventing a system of such a complexity as language.

By announcing the prize topic as being the origin of language in 1769, the Berlin Academy endeavored to find a persuasive solution that defended the possibility of human invention. Scholars considered the question as highly important, 31 essays were submitted to the Academy, an unusually high number of entries. Today, 24 of the manuscripts are still to be found in the archive of the *Berlin-Brandenburgische Akademie der Wissenschaften*. They constitute an important *text series* in the field of language origin study. Only the winning essay of Johann Gottfried Herder (1744–1803) (see Figure 7) has traditionally been considered a milestone of the Enlightenment's conception of language origins. According to Herder, the emergence of language was due to the so-called *Besonnenheit*, an intrinsic disposition of man predating reflection and permitting man to listen carefully to the sounds of his surroundings and to retain the most impressive sounds (e.g., the bleating of a sheep) as internal marks (*innere Merkworte*).

An analysis of the remaining entries (cf. Neis, 2003) revealed the existence of recurrent *topoi* and commonplaces in the arguments of the different participants. As the genesis of language is beyond historical

Figure 6 Hobbes. Drawn by Klaus Froese.

Figure 7 Herder. Drawn by Klaus Froese.

times, it can only be guessed at by means of hypothesis. Among the most recurrent *topoi* used by the participants on the origin of language question were the process of language acquisition among infants and the analysis of several hypothetical groups whose acquisition of language was impaired, such as *feral children*, the deaf and dumb, and exotic peoples. It was social, physical, or cultural deprivation that caused the exclusion of these individuals from a normal process of language acquisition.

The Origin of Language Topic in the 19th and 20th Centuries

Although the Berlin Prize contest had highlighted the debate on the origin of language in the 18th century, in the course of the 19th century, scholars continued to engage themselves in the discussion (see the contributions of Jacob Grimm (1785–1863), Wilhelm von Humboldt (1767–1835), Max Müller (1823–1900), Lazarus Geiger (1829–1870), etc.). Innovative theories were developed, partly influenced by the Darwinian paradigm and inspired by the solid empirical studies in emerging fields such as phrenology and neurology. The flood of contributions to the problem of the origin of language incited the *Société linguistique de Paris* in 1866 to ban the academic treatment of this topic within its institutional confines. By the end of the 20th century, this verdict became obsolete, and research on the origin of language was not limited to the language sciences, but became a pivotal topic for several interdisciplinary scientific domains.

Paradoxes, Semantic

T Kenyon, University of Waterloo, Waterloo, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

The semantic paradoxes are a group of logico-linguistic puzzles characterized by the key roles of semantic notions such as truth, reference, or meaning in their construction. Like any paradox, their defining feature is that they force us to accept absurd consequences without employing any premise or concept that can easily be rejected. The semantic paradoxes are usually grouped together for the purpose of distinguishing them from the logical or set-theoretic paradoxes, the most famous of which are Russell's Paradox, Cantor's Paradox, and the Burali-Forti Paradox. The depth of difference between these two groups is not always clear, however, so it is unwise to attach much significance to the distinction.

The Paradoxes

The most significant of the semantic paradoxes, the Paradox of the Liar, is also the most ancient, dating at least to the 4th century B.C.E. Eubulides of Miletus is the first known writer to have formulated it as a fairly explicit logical puzzle. In a still earlier form, the Paradox (often simply called 'the Liar') consisted of an utterance attributed to the philosopher Epimenides, who was said to have framed the implicitly puzzling statement 'All Cretans are liars.' The idea was that since Epimenides himself was a Cretan, his statement, if true, would be false. An allusion to this forerunner of the puzzle even surfaced in a biblical reference from the letter to Titus, whose author seemed to take Epimenides' example rather too literally: "Even one of their own prophets has said, 'Cretans are always liars...'" In any case, this version turns out not to be very obviously paradoxical, since one need not always lie in order to count as a liar. One could be a lying rascal in general who happens to be telling the truth just this once.

Avoiding some of these quibbles, Eubulides simply asked whether someone who says 'I am lying' speaks truly or falsely. This is a better paradox, though still somewhat confounded by the fact that while lying entails speaking a falsehood, the converse does not hold. If the speaker is lying, then by the meaning of 'lying' the utterance is false; but if the utterance is false, then it does not quite follow that what he says – namely, that he is lying – is true. One can speak falsely without lying. The most obviously paradoxical version of the puzzle, then, is the still simpler case 'This sentence is false.' While this may be intuitively paradoxical, we can make the problem transparent by adding explicit assumptions: Any well-formed sentence *P* in the indicative mood is true just in case *P* and is false otherwise; the Liar sentence is such a well-formed sentence; and the expression 'this sentence' in the Liar sentence refers to the Liar sentence itself. So assume that the Liar sentence is true. What it tells us, though, is that it is false. So if it is true, then it is both true and false. Now assume that it is false. Then, since the Liar sentence tells us that it is false, what it tells us is true; if false, it is both true and false. Whether we take the Liar to be true or false in the first instance, we are forced us to accept a contradiction. Yet by our first assumption it must be either true or false, so we seem committed to the contradiction. Variants of the paradox include the Strengthened Liar ('This sentence is not true'), which dispenses with the assumption that 'false' means 'not-true,' and sets of sentences as in the postcard paradox (supposing a postcard that reads on one side 'The sentence on the other side of this card is true,' and on the other side, 'The sentence on the other side of this card is false'). Various responses to the Liar are summarized later in this article.

Other well-known semantic paradoxes have more recent origins. The Grelling-Nelson Paradox (sometimes just known as Grelling's Paradox, or the Heterological Paradox) dates from a 1908 paper discussing Russell's Paradox and the Burali-Forti Paradox. Grelling and Nelson's example is based on

a seemingly innocuous adjective. Adjectives, of course, are descriptive terms. Among the things they can describe are words, and among the words an adjective might describe is that adjective itself. So, for example, the adjective 'linguistic' is linguistic, just as the adjective 'short' is short and 'polysyllabic' is polysyllabic. Call adjectives that describe themselves *autological*. On the other hand, most adjectives do not describe themselves. 'Long' is not long, 'wet' is not wet, and 'plebian' is not plebian. Call adjectives that do not describe themselves *heterological*. Notice, though, that both 'autological' and 'heterological' are themselves adjectives. So are these two adjectives themselves autological or heterological? In particular, is 'heterological' heterological? In order to be heterological, the adjective must not describe itself and hence not be heterological; yet if not heterological, it is non-self-describing, and hence is heterological. It describes itself if and only if it does not.

A semantic paradox of definability is Berry's Paradox. There are two versions of it, the lesser known being the more historically accurate. In 1904 Berry wrote to Russell, suggesting a paradoxical definition: "the smallest ordinal number that cannot be defined in finitely many words." Of course, this definition defines such a number in finitely many words, yielding a contradiction. Russell later published a different paradox, which he named after Berry and which is the more familiar version: Consider the least integer not nameable in fewer than 19 syllables. We just defined (loosely, named) this integer in 18 syllables, however, so a contradiction is forthcoming: the least integer not nameable in fewer than 19 syllables is nameable in fewer than 19 syllables.

Another paradox of definability, resembling both Berry's and Cantor's paradoxes, is Richard's Paradox. Imagine a numbered infinite list of all English phrases that pick out exactly one positive real number. Now consider this definition: the positive real number having in its decimal expansion, at the n th position after the decimal, a 1 if the number defined by n th entry on the list has a 0 in its n th position after the decimal, and a 0 otherwise. This seems to define a number and hence must be an entry in the list. By hypothesis, however, any number thus identified cannot be defined by any entry on the list, since for any n th entry on the list, the Richard number differs from that entry in the n th position after the decimal. So this definition cannot be an entry in the list.

Both Berry's and Richard's paradoxes are usually diagnosed as arising from inherent imprecision in the concept of definition. Whether some definition is

formulable (and in how many words or syllables) is clearly contingent upon features of the particular language in question. When a suitably precise definition is given for definability itself – explicitly relativized to a language – that is, *definable in L* – the air of paradox is dispelled.

Suggested Solutions to the Liar

An analogous explanation is typically applied to the standard example of a semantic paradox, the Liar, the literature on which is both the most extensive and the most intellectually fertile of any on the various paradoxes. The most significant and technically developed interpretation of the Liar diagnoses the problem in terms of imprecision in the semantic notions found within natural language, and particularly the notion of truth.

Alfred Tarski gave the first rigorous expression of this line of thought, arguing that a natural language like English, with its apparently univocal predicate 'is true,' is a semantically closed language. This means that when one predicates truth of a declarative sentence S in English, the result is another English sentence, S is true. And this new sentence is in turn subject to the application of the same truth predicate – and the same, *mutatis mutandis*, goes for the predicate 'is false.' Tarski argued that the contradictions arising from the Liar are an artifact of semantic closure, hence showing that natural languages cannot be understood as employing a logically coherent concept of truth. The coherent idea approximating the ordinary notion is really that of *truth in L* : truth relativized to a language, where this means a formally defined language rather than a natural language. We have to refine our use of the truth predicate by viewing it as the application of a *metalanguage* to an *object language*, in the terminology Tarski coined. Of course, since any metalanguage can in turn be characterized by yet another language, the designations of object language and metalanguage are relative. On this view, to apply 'is true' to a sentence in a logically consistent way is to use a language of a semantic level distinct from that of the sentence to which the predicate is applied: we apply a metalanguage predicate to an object language sentence. Reading the Liar sentence as an attempt to apply the truth predicate of L to a sentence of L , we can use the Tarskian diagnosis to conclude that the Liar is simply ill formed rather than paradoxical.

Tarski's proposal and its ancillary details have been an important source of insights in logic and the

philosophy of language. Notwithstanding its great influence, however, it is not generally accepted as a solution. Some writers object that natural language does not seem to contain the hierarchy of notional languages defined by Tarski. It is not clear that this complaint engages Tarski's precise view, however; he claimed, rather, that the machinery of object language and metalanguage is *imposed* on fragments of natural language for analytic purposes. Another class of objections is perhaps closer to the mark: Tarski's conclusion that the truth predicate must belong to a language 'essentially richer' than the language of which it is predicated is neither perfectly clear in its formal definition nor entirely plausible as applied to many Liar-like cases.

As Saul Kripke argued, there seem to be many cases in which linguistically internal applications of a univocal truth predicate are not ill formed. Suppose Jill's only utterance about Larry is 'Most of what Larry says about me is true.' Larry, then, might say only the following about Jill: 'Jill is a banker; Jill went to Athabasca College; everything Jill says about me is false.' In the event that Larry's first two statements are true, there is no temptation to find ill-formedness in either utterance: Jill's statement is true, and Larry's third statement is straightforwardly false. But should only one of Larry's first two statements be correct, then Jill's statement will be true just in case Larry's third statement is true. Yet this says Jill's statement is false, making Larry's third statement false as well; it is now essentially the postcard version of the paradox. Here the Tarskian analysis seems misplaced. For how could nonlogical, nonlinguistic facts like Jill's profession determine whether her statement and Larry's third should count as inherently ill formed? Kripke's solution was to reject the principle of bivalence that enables the inference from *S is not true* to *S is false*. Both truth and falsity attach to grounded statements, by which Kripke meant those whose truth conditions do not ultimately implicate truth itself. Ungrounded statements, including the Liar, are neither true nor false.

Kripke's solution, too, is not regarded as decisive. At the metalinguistic level, at least, Kripke's theory seems to inherit the *Strengthened Liar* paradox: 'This sentence is not true.' Intuitively this sentence correctly describes itself whether it is false or ungrounded, and so is true just in case it is not true. The Strengthened Liar is generally taken to be the strongest version of the paradox, the version that any successful solution must address. There is currently no consensus on

how best to go about formulating such a solution. Some devotees of the puzzle continue in the Tarskian tradition, while some advocate an explanation in terms of language pragmatics or faulty presupposition; utterances of the Liar are said to amount to a sort of performative misfire on this view. Still other approaches proceed via nonstandard logics, an example of which is *dialetheism*, a kind of paraconsistency that tolerates the existence of statements that are both true and false. The Liar is suggested as an example of such a statement. As a paraconsistent approach, dialetheism rejects *ex falso quodlibet*, the classical 'explosion' principle by which the consequences of contradictions ramify without constraint. The dialetheist proposal depicts the Liar as a surprising and idiosyncratic, but logically tolerable, true-and-false statement while limiting permissible inferences from such contradictions in order to keep the idiosyncrasy localized. It is unclear what motivation can be given for this proposal, however, except for the difficulties of other attempted solutions.

Philosophy of Linguistics

P Carr, Université Paul Valéry, Montpellier, France

© 2006 Elsevier Ltd. All rights reserved.

The philosophy of linguistics concerns itself with the nature of human language and of linguistic inquiry. The central issues concern epistemology and ontology. 'Epistemology' is the branch of philosophy dealing with the nature of knowledge – in this case linguistic knowledge. 'Ontology' is the branch of philosophy dealing with reality, with what exists (is there only one kind of reality, or should we speak of a pluralism of realities?). In the philosophy of linguistics, the main ontological question is whether we can reasonably claim that there are linguistic realities, or a single linguistic reality, as distinct from other kinds of reality. Epistemology and ontology are closely intertwined, especially if we assume that there are linguistic realities, and that they constitute a kind of knowledge. The philosophy of linguistics is closely connected with issues in the philosophy of science, which concerns itself with questions such as: is there such a thing as scientific knowledge, distinct in kind from other sorts of knowledge? Is it possible to distinguish scientific theories from other sorts of theory? If so, how? Is there such a thing as a scientific method? If so, how do we characterize it? What makes it different from other methods? Clearly, we cannot say whether, or to what extent, linguistic inquiry might be scientific unless we have some sense of what we mean by 'science.' Furthermore, given that philosophers of science disagree on the answers to the questions just raised, linguists must adopt a particular philosophy of science if they are to argue that linguistic inquiry is scientific in nature.

To set out the range of positions that have been proposed in the philosophy of linguistics, let us begin with a distinction made within the philosophy of science literature and then relate it to positions adopted within linguistics. Some philosophers of science, notably Feyerabend (1975), argued that there is no valid distinction to be drawn between scientific and nonscientific knowledge, that the idea of 'scientific method' is an illusion. Those who have denied this include Popper (1959), who argued that there is such a thing as scientific method, and thus scientific knowledge, distinct from nonscientific knowledge. But he disagreed with the views of the members of the Vienna Circle, a group of scientists and philosophers working in the Vienna in the mid-20th century, who embraced a position known as 'logical positivism.' The logical positivists (e.g., Moritz Schlick) argued that scientific knowledge is firmly and exclusively based on

observation, and that, because of this, scientific theories, unlike nonscientific theories, can be proven, yielding knowledge that was certain (indubitable). They went further than this: they argued that statements that are not scientific (on their understanding of the term) are literally meaningless. Their position is often referred to as 'verificationism,' since they believed that scientific theories could be verified (proven) via observation of the physical world. Although Popper believed, like the logical positivists, that there was such a thing as a scientific method, and thus scientific knowledge, he disagreed with the idea that science yields certain knowledge via verification. Instead, he argued for 'fallibilism,' the idea that our scientific hypotheses are always fallible, and that we can never have knowledge that is absolutely certain. Popper rejected verificationism and adopted, in its place, 'falsificationism': he believed that the hallmark of scientific hypotheses was falsifiability: if a claim about the world was framed in such a way that it admitted of counterevidence, then it was falsifiable and thus scientific. There is a connection between this idea and the idea of the content of a hypothesis: the more a hypothesis excludes (the more states of affairs it rules out), the more it is claiming about the world. Popper believed that scientific inquiry rested on a process of hypothesis formation, deduction of the consequences of our hypotheses, and testing of those consequences. This is known as the 'hypothetico-deductive method.' If a falsifiable hypothesis is tested and falsified, then we may retain it until a better hypothesis emerges, abandon it, or modify it. For Popper, this was what allowed us to make scientific progress. But even if a testable hypothesis has not been falsified, that does not warrant the conclusion that it is true: for Popper, our scientific knowledge was always open to the possibility of being falsified and abandoned. Popper also rejected the view that nonscientific claims were meaningless. In its place, he argued that a given idea may begin by being nonscientific (unfalsifiable) but nonetheless meaningful, to being falsifiable, and thus scientific. An example he gave of this was the idea that the earth revolved around the sun, an idea that has its roots in Greek mythology but that eventually became scientific.

Popper's views on the scientific method were combined with another central plank in his philosophy of science: 'scientific realism.' By this he meant the idea that there are aspects of reality that are amenable to scientific inquiry but are not themselves directly observable. Examples of these are gravitational force and electromagnetic forces: we cannot, in principle, observe these, but we can observe their effects. For

Popper, it was thus valid for scientists to postulate unobservable aspects of reality and to make testable claims about them. This clearly flew in the face of the positivist claim that scientific knowledge concerns only that which is observable. Opponents of scientific-realism adopted a position referred to by Popper as 'instrumentalism,' since they argued that theoretical constructs in science were no more than that: they were instruments for systematizing and making predictions about observable phenomena. Under an instrumentalist approach, we are not warranted in saying that our constructs correspond to theory-external objects and events in the world. The term 'phenomenalism' is also used for this position. Thus, all talk of unobservable 'forces' is nothing more than a way of talking about observable phenomena: the instrumentalist withholds any ontological commitment of the sort that claims that various forces actually exist.

The distinction between positivism, with its instrumentalist, antirealist outlook, and scientific realism had an effect on modern linguistics. During the mid-20th century, many linguists (notably, the 'post-Bloomfieldians') working in the United States argued for an instrumentalist interpretation of linguistic constructs, such as 'the phoneme' and 'the morpheme.' It is arguable that they had been influenced by the logical positivists, either directly or indirectly. In insisting that linguistics, to be scientific, had to concern itself only with that which was observable, they were committed to a position that was antimentalistic, since mental states and processes are, by definition, unobservable. This outlook was combined with a positivistic conception of psychology, often referred to as 'behaviorism,' the view that a properly scientific psychology should concern itself only with observable behavior and not with unobservables.

It is arguable that much of Noam Chomsky's thinking (1965, 1993, 2002 and elsewhere) about the nature of linguistic inquiry is in line with Popper's thinking about science. Like his immediate predecessors in the United States, Chomsky believed that the kinds of linguistic inquiry he was engaged in (generative linguistics) were scientific in nature. But, unlike them, Chomsky adopted scientific realism: he argued that science is not limited to observables. It is Chomsky's scientific realism that allowed him to embrace mentalism in the study of language: freed from the insistence that science concerns itself only with that which is observable, Chomsky could allow that there are linguistic realities that are mental in nature, in stark contrast to the antimentalistic stance of his immediate predecessors. He went further than this: he insisted that linguistic realities are exclusively mental. More specifically, they are mental states, not processes, and they are strictly internal to individuals. Thus,

linguistic inquiry was a branch of individual psychology for Chomsky. This clearly flies in the face of any social conception of the object of linguistic inquiry, which Chomsky labeled 'E-language,' where the 'E' means 'external to individual minds.' In contrast, he insisted that the object of inquiry in linguistics is 'I-language,' where the 'I' stands for both 'Individual' and 'Internal' (to the mind). This is Chomsky's 'internalism.' Connected with this is Chomsky's insistence that language is not designed for use. This is not intended to mean that language is not, in fact, used for communication (no one could deny that it is); rather, communicative use is not what language is for. This is Chomsky's 'antifunctionalism': in his view, language is not driven by communicative function. Rather, language is for thinking: language and thought are intimately connected, for Chomsky. Connected with this is the long-standing distinction between 'competence' and 'performance': for Chomsky, the object of inquiry is not observable utterance phenomena (performance), or acts of online mental processing of utterances (which also falls within performance), but the knowledge (competence) that allows performance (use of that knowledge) to take place. The choice of terminology was unfortunate, since in everyday parlance, 'competence' denotes the ability to perform in some domain, as in *John's competence as a manager is unquestionable*. But Chomsky long since insisted that his conception of linguistic knowledge was not to be interpreted as knowing how to do something; nor was it to be interpreted as knowing that something is the case. Rather, linguistic knowledge was an unconscious mental state that grew in the mind of the child.

This notion of growth is a biological one: according to Chomsky, language 'acquisition' (the term is inappropriate in discussing Chomsky's views, since, for Chomsky, language is not acquired – it is innate) was not something that a child did: it was something that happened to the child. In this view, 'language acquisition' is a process of biological growth. This constitutes Chomsky's 'naturalism': the view that language belongs to the natural world and not to culture, a view that is controversial. A central component of Chomsky's naturalism was his claim that human beings are born with linguistic knowledge, that there is innate cognitive content that is specifically linguistic. This is often referred to as the 'innateness hypothesis,' although Chomsky disliked the term on the grounds that everyone agreed that there are innate cognitive capacities: the question is what they might be. In arguing for innate linguistic knowledge, Chomsky adopted a version of 'rationalism,' often referred to as 'nativism.' In the history of philosophy, rationalism is most frequently associated with the

work of René Descartes, who argued that not all human knowledge is acquired through interaction with the mind-external world. Rather, he argued that there is innate cognitive content, often referred to as the 'Cartesian doctrine of innate ideas.' Chomsky explicitly associated himself with the Cartesian tradition and has elaborated a specifically linguistic version of rationalism. The Chomskyan version of the doctrine of innate ideas is that we are born with a universal set of semantic primitives, out of which specific word meanings are constructed. Although the terms 'nativism' and 'rationalism' tend to be used interchangeably, some definitions of nativism claim only that it amounts to allowing that there are innate cognitive capacities, a view that is consistent with 'empiricism,' a doctrine that has various versions, but that emphasizes the role of our experience with the mind-external world in acquiring knowledge. Empiricists need not deny that we are born with innate cognitive capacities of various sorts (such as the capacity for forming inductive and analogical generalizations); where empiricists in linguistics disagree with Chomsky is in denying that innate, specifically linguistic, knowledge exists.

Another central plank in Chomsky's philosophy of linguistics is his adoption of 'modularism,' the view that at least some aspects of the mind are modular in nature. By 'module' he meant a distinct component of mind devoted to a specific cognitive domain (such as language, or recognition of familiar faces, or the visual system as a whole). The notion of modularity of mind is associated with the work of Fodor (1983), who suggested a set of defining properties of mental modules, including the property of being 'encapsulated.' The idea behind encapsulation is that the internal workings of a mental module are unavailable to other aspects of the mind. However, the output of a module is available to other aspects of the mind. For instance, we cannot access the inner workings of the module of mind that compels us to suffer optical illusions, but we do access the output of that module. Like Fodor, Chomsky never believed that the mind is entirely modular, but he did consistently espouse linguistic modularity: he believed that the mind contains an innately endowed language module. He also followed Fodor in believing that the mind contains a central processor that is nonmodular and that is used in, among other things, the fixation of beliefs. Our experience of optical illusions provides us with an example of the distinction between the modular visual system and the central processor: while the central processor can arrive at the belief that a given picture constitutes an optical illusion, it cannot override the output of the visual system. Knowing that a picture is illusory does not allow us to escape from

experiencing the illusion. Fodor claimed that the central processor contains a 'Language of Thought' (LoT), which is said to be innate. The LoT is said to be a universal set of semantic primitives that has a syntax of its own, allowing for the construction of complex concepts out of a set of semantic primitives. One of the arguments in favor of the LoT is the claim that language acquisition involves entertaining hypotheses about the structure of the language to be acquired: such hypotheses cannot be formulated unless there is an innate LoT for them to be formulated in. One important difference between Chomsky and Fodor is that, when Fodor spoke of language as a mental module, he conceived of it as an input/output module that receives certain kinds of output from the mind-external world, processes it, and creates an output. For Chomsky, input/output modules were distinct in kind from the innermost cognitive system, which constitutes language.

An alternative recent approach to modularity can be found in the work of Karmiloff-Smith (2001), who argued that, rather than postulating innate mental modules, we should postulate, in addition to general cognitive capacities, innate biases in certain domains, which then evolve into a modular organization. This notion of emergent modularity is part of Karmiloff-Smith's 'constructivism,' according to which a child actively constructs a mental grammar, revising his or her own internal representations during the course of development. This stands in contrast to Chomsky's passive conception of language acquisition. The work of Karmiloff-Smith occupies a midway position between rationalism and empiricism. A more overtly empiricist approach to linguistic knowledge was adopted by the linguist Geoffrey Sampson (1997), who opposed linguistic rationalism for several decades. Sampson claimed that the arguments given in support of nativism do not hold up to close scrutiny. Instead, he argued that the child starts with a blank slate, but with the capacity to learn via the hypothetico-deductive method. On this view, language acquisition is learning, a view entirely at odds with the Chomskyan view.

Others have objected to the ontological status of linguistic objects proposed by Chomsky. Among these are Katz (1981), who argued for Platonism in linguistics. Arguing against Chomsky's psychologism (the view that linguistics is a branch of psychology), Katz's view, which is a version of realism, was that there are linguistic realities but they are 'abstract,' in the sense of being Platonic in nature: they are not spatio-temporal (they do not exist in space and time). Katz was a semanticist who argued, among other things, that the existence of necessary truths in language leads us inexorably to Platonism, since necessary

truths are timeless: they predate human psychological states. Katz also argued that, since the notion 'knowledge of' is a two-place predicate, the notion 'knowledge of language' presupposes linguistic objects of which we have mind-internal knowledge. Knowledge of the structure of a sentence, Katz argued, is distinct from the structure of the sentence *per se*. Engaging in acts of intuitive grammaticality judgment entailed, Katz claimed, our gaining direct access to abstract Platonic objects, rather than gaining access to mind-internal states, as Chomsky argued. Note that Chomsky's use of the term 'knowledge' did not, in fact, appeal to a two-place predicate: linguistic knowledge was not knowledge of something, for Chomsky. Katz argued not only that linguistic objects such as sentences were Platonic objects, but that specific languages such as French and Spanish also had this status. For Katz, linguistics was on a par with mathematics, as one of the 'sciences of the intuition': just as mathematical objects are (according to Katz) mind-external Platonic objects to which we can gain intuitive access, so are sentences. A less radical version of antipsychologism was the view, first proposed by Roger Lass (1976), that linguistic objects are intersubjective in nature, specifically that they belong to the ontological category referred to by Popper (1972) as 'world three.' Popper argued for 'ontological pluralism,' the view that the world is open-ended and that new sorts of reality can emerge. For Popper, 'world one' was the world of inanimate physical objects and events. 'World two' was the world of mental states, which emerged with the emergence of life forms, particularly those with minds. 'World three' was where Popper believed scientific knowledge belonged: he regarded scientific theories as objective knowledge, intersubjective in nature. His principal argument was that our scientific theories may contain logical consequences that might, at a given stage in scientific history, remain unnoticed, later to be discovered. Popper believed that such consequences are real, even before being discovered, and that they therefore must be said to exist independently of our subjective mental states. Carr (1990) later elaborated on Lass's idea, arguing that linguistic knowledge is objective knowledge in the Popperian sense, while also arguing that generative linguistics is scientific in the Popperian sense.

A distinct version of linguistic knowledge as mutual knowledge can be found in the work of Itkonen (1978), who argued that the central notion in language is the notion of socially constituted rules or norms. Itkonen distinguished spatiotemporal events such as rocks rolling down hills, from our actions, which necessarily contain a component of intentionality. It is social actions that are central to Itkonen's

thinking: he argued that socially constituted norms (rules) formed the basis for linguistic behavior. These norms (conventions) are the object of grammatical inquiry for Itkonen, and since they are social in nature, the object of grammatical inquiry is social, not mind-internal.

A more recent approach to the question of the respective roles of nature and social conventions can be found in the work of Noel Burton-Roberts (see Burton-Roberts and Carr, 1999). Burton-Roberts adopted a version of naturalism; he advocated 'radical internalism,' the view that the only coherent conception of Chomskyan internalism is one under which the contents of innate linguistic knowledge are not in any sense internalized. 'Internalization' implies setting up mind-internal representations of events or objects that are mind-external. This, Burton-Roberts argued, is not what Chomsky intend when he advocated internalism. He agreed with Chomsky that radically internal language is 'austere' in the sense that it has no access to other aspects of mind that contain internalization of properties of the mind-external world, such as linearity (sequentiality), derived from the linear sequencing of the speech signal. Knowledge of the conventions regarding the sequences of phonemes, morphemes, and words in a specific language is 'internalized knowledge' for Burton-Roberts. The place of phonology was a central concern for Burton-Roberts (see Burton-Roberts 2000), since sequencing is a defining feature of phonology. The relationship between phonology and semantics was equally important for Burton-Roberts, since that relationship was both arbitrary and conventional. He argued that if one allows, as Chomsky did, that phonological knowledge is part of radically internal linguistic knowledge, then one compromises radical internalism by incorporating that which is conventional into that which is natural. The distinction between that which is radically mind-internal and that which is internalized is crucial here. That which is radically internal to the mind has not been internalized from the mind-external world. That which is internalized, such as the mental image of a familiar face, is not radically internal: it results from internalizing aspects of the mind-external world.

Burton-Roberts distinguished a generic conception of language from the Chomskyan naturalistic conception of language. The former appealed to a notion of the universality of the notion 'language' by generalizing over all human languages: 'language' here is the generic term for the set of all languages. In this view, a specific language is an 'instantiation,' or 'token,' of the type 'language.' The generic conception of language lends itself to an instrumentalist interpretation: the notion 'language' can be seen as a construct

that has no reality beyond the specific languages which it ranges over. The naturalistic conception of language appeals to a notion of 'language' as something quite independent of particular languages: the reality of language, in this view, does not reside in particular languages. Rather, 'language' is the innate linguistic knowledge shared by all members of the species. The naturalistic conception of language lends itself to a realist interpretation: 'language' as a biological reality. The generic conception of 'language' embodies a methodological claim: that the way to understand the notion 'language' is to investigate particular languages. In this view, strong universals are properties attested in every human language that one will ever encounter, whereas weak universals are tendencies within the world's languages. The naturalistic conception, on the other hand, embodies an ontological claim: that the notion 'language' denotes an object in the biological world. Universals here are the properties of that object. Burton-Roberts argued that Chomsky's conception of I-language is inconsistent in that it vacillates between the generic and the naturalistic conceptions of language. This is so because Chomsky takes phonology, and thus linearity, to constitute part of naturalistic I-language. For Burton-Roberts, linearity and conventionality necessarily lay outside of language conceived of in naturalistic terms (since conventions are social in nature: they belong to culture, not nature; conventions are not given by biology). Crucially, Burton-Roberts argued that Chomsky was mistaken in regarding the relationship between 'language' (understood in the naturalistic sense) and particular languages as one of instantiation, since this amounted to incorporating an aspect of the generic conception into the naturalistic conception. Burton-Roberts argued that, if we are to sustain the naturalistic conception, we must replace the relation of instantiation with one of 'physical representation': specific utterance phenomena are mind-external physical representations of the contents of the language module. Burton-Roberts was at pains to point out that physical representation is entirely distinct from instantiation: that which is a physical representation of something is not thereby an instantiation of it, just as Magritte's painting of a pipe is not itself an instance of a pipe. For Burton-Roberts, particular languages are acquired, phonologically constituted, conventional systems for physically representing a single, natural, innate language. Burton-Roberts's main epistemological point was that knowledge of the representational conventions of a specific language is quite distinct from innate linguistic knowledge: it is acquired, internalized from the mind-external world. It is conventional, not natural, in character. Burton-Roberts was thus able to

accommodate many aspects of empiricism (such as implicit and explicit learning, analogical and inductive generalization) into his conception of the acquisition of a language, while retaining Chomskyan rationalism. Interestingly, Burton-Roberts's position raises the question of whether there is any distinction to be made between the idea of an LoT and the idea of an innate language module: both have been said to contain a universal set of semantic primitives and a recursive combinatorial syntax, yielding linguistic expressions that have hierarchical structure. If no distinction is to be drawn between the two, then innate language is simply the innate LoT, which is nonmodular in nature. One then ends up with a version of naturalism that denies that there is a language module, while allowing that our knowledge of conventions of physical representation may become modular in the course of development.

Another recent approach to the language-versus-culture debate surrounding the nature of linguistic knowledge is that adopted by Levinson (2001, 2003a, 2003b). Levinson and colleagues resuscitated a version of the Sapir-Whorf Hypothesis, according to which the categories of the language one has acquired shape, to some extent, cognitive content and mental activity. Levinson claimed that, on the basis of a wide sample of languages, it is possible to conclude that there are three main kinds of Frame of Reference (henceforth FoR) for expressing the spatial location of an object relative to other objects on a horizontal plane. First, there is an 'egocentric' (viewpoint-dependent) or 'relative' FoR (what counts as left or right is relative to one's location: turn around 180 degrees and right becomes left), as in *The ball is to the left of the tree*. Second, there is a 'geocentric' or 'absolute' FoR (what counts as north or south is not relative to one's location), as in *The ball is to the north of the tree*. Third, there is an 'object-centered' or 'intrinsic' FoR. This latter kind of FoR involves locating an object A with reference to the partitioning of another object B into parts and the projection of an axis from the centre of object B through one of its parts, as in *The ball is at the front of the truck* (Levinson, 2003a: 8), where object A is the ball, object B is the truck, and the relevant part of object B is the front of the truck.

Levinson claimed that it has been assumed by nativists that concepts such as 'left' and 'right' are universal, since they are necessarily innate in the nativist view. Crucial to Levinson's argument is the claim that not all languages possess all three systems, but that any given language will possess at least one. Note that the conception of universalism appealed to here is the generic conception, not the naturalistic one: Levinson's argument here does not necessarily undermine a consistently naturalistic conception of

the notion 'language.' Importantly for Levinson, some languages (e.g., Oxchuc Tzeltal, an American Indian language spoken in Mexico) have no 'relative' spatial expressions at all. In such languages, one cannot say *The ball is to the left of the tree*; rather, one has to express the spatial location by means of absolute terms, such as *The ball is north of the tree, Please pass the plate to your east*, or *Take the first turning to the south* (but not *Take the first turning on the right*). Equally, in work with Majid *et al.* (2003), Levinson and colleagues argued that speakers of the Australian language Guguyimidjir entirely lack both relative and intrinsic FoRs and use only absolute FoRs, so that even the description of the location of an object on a body part is described, and conceived of, in absolute terms, as in *There's an ant on your south leg*. Levinson argued that the conceptual representations we use in nonlinguistic thinking vary depending on the language we have acquired, a strikingly Whorfian claim that has incited opposition among broadly Chomskyan linguists such as Li and Gleitman (2002). Levinson and colleagues carried out experiments in which a set of languages were classified as absolute, relative, or mixed and required speakers of those languages to carry out nonlinguistic tasks involving the spatial location of objects. In one such task, reported in Levinson (2001: 578–579), subjects were shown three different toy animals in a row on a table and asked to memorize the order in which they appeared. The subjects were then turned around by 180 degrees, taken to another table, and asked to place the objects in the same order they had seen them in. When he compared speakers of Tzeltal, who have a language with an absolute FoR to describe objects in a row, he found that they placed the objects in the opposite order from the way they were placed by speakers of Dutch, which uses a relative FoR: the subjects seemed to be memorizing the rows of objects in a way that was consistent with the FoR given by their native language.

The claims made by Levinson are clearly of considerable importance in debates about the nature of language, since they rest on the claim that both nature and culture play a role in linguistic knowledge. For Levinson, there is coevolution of language, nature, and culture, and cultural variation subsumes linguistic variation, which results in variation in 'cognitive style.' Levinson's work offers new empirical observations on the relative roles played by nature and culture in human language.

Philosophy of Science and Linguistics

C Wearing, University of Western Ontario, London, Canada

If linguistics is the science of language, we might begin by asking what kind of science it is. One answer, which has been given its major impetus by the work of Noam Chomsky, is that linguistics is a branch of psychology. A second answer, in some tension with the first, is that linguistics is a branch of mathematics. There are other possibilities, too: some view linguistics as a social science like anthropology, whereas others reject the idea that it is a science at all, taking it to be continuous with literary theory. In this article, we focus on the first two answers, as these answers have both arisen within a tradition of taking language to be a generative phenomenon (something that is built up from various component parts via rules of combination). The other possibilities, by contrast, tend to view language as considerably less systematic, amenable chiefly to the description of comparatively superficial regularities.

Depending on whether one regards linguistics as psychology, then, or as mathematics, the following questions receive very different answers: What are the characteristic methods of study in linguistics and what evidence does it employ? What does linguistics aim to discover and explain? And how is linguistics related to other scientific domains? In what follows, we examine the answers that the psychological and the mathematical positions offer to these questions. But to begin, we must examine the object of that enquiry – language – and consider what a language might be, that its study should constitute psychology or, alternatively, mathematics.

The starting point of any scientific enquiry must be its object of study, because the way in which this object is conceived determines what one aims to explain. In the case of linguistics, Chomsky's work (e.g., Chomsky, 1957, 1965) brought about a substantial shift in the conception of language, importantly altering the goals of linguistic enquiry. During the first half of the 20th century, the predominant view conceived of language as an external object, the totality of marks and noises produced by language speakers. For structuralist linguists such as Ferdinand de Saussure and Leonard Bloomfield, linguistics was chiefly a descriptive enquiry, looking for patterns exhibited across the elements of the linguistic corpus. Chomsky's proposal, by contrast, was to regard language as essentially something internal, namely, as a competence underlying the speaker/

hearer's ability to produce and understand the sounds and marks on which the structuralist was focused. On this view, language is an internally represented (implicit) system of knowledge that an individual speaker possesses, rather than the collection of sounds or marks that she is able to understand. Her language – this knowledge of linguistic rules and structures – is what allows her to understand such (external) objects.

In contrast with this position, several philosophers (Lewis, 1975; Katz, 1981; Soames, 1985; Devitt, 2003) have argued that this sort of internalist view of language is mistaken – that the structuralists were not wrong to view language as external – at least when it comes to doing linguistics. Unlike the structuralists, however, they treat languages as abstract external objects, namely, collections of sentences akin to the languages of formal logic. From this point of view, Urdu and Hungarian are on a par with the language of first-order logic: they are abstract formal systems governed by recursive grammatical rules and possessing canonical interpretations that assign meanings to their sentences. But regarded as such, languages are purely mathematical objects; psychology is not relevant to describing the properties of such entities.

For the proponent of the mathematical view, then, linguistics is an investigation of the grammatical and other structural features of languages, conceived of as abstract collections of sentences. It is, of course, compatible with this view that speakers know a grammar that allows them to understand and use the language they speak, and psychology (specifically, psycholinguistics) may tell us about the linguistic abilities of speakers and hearers. But on this view, psycholinguistics and linguistics are distinct enterprises: the former studies human psychology, whereas the latter studies abstract mathematical entities that are importantly independent of human psychology.

Thus, the goal of the mathematical linguist is to exhibit a grammar for the language being studied. As a matter of mathematical fact, there will be indefinitely many equivalent grammars for any given language, so to the extent that a language is considered in abstraction from any psychological basis it might have, there is no particular requirement that the linguist seek the grammar that the speakers of the language actually know. In a similar way, there is no reason to seek a grammar that is sensitive to regularities exhibited across multiple languages. Any grammar that is descriptively adequate, i.e., that generates all and only the grammatical sentences of the language in question, satisfies the goal of the mathematical linguist.

The principal evidence available for this undertaking consists in the judgments of native speakers about

the acceptability of sample sentences: are the sentences well formed? Are they meaningful or senseless? To borrow some well-known examples, English speakers judge that sentence (1) is an acceptable sentence of their language but (2) is not. Sentences (3) and (4) are both structurally (grammatically) acceptable, but they have notable meaning-related features. Sentence (3) has two distinct interpretations, whereas (4) arguably lacks any coherent interpretation:

- (1) The cat scratched the child.
- (2) *Cat the child the scratched.
- (3) Everyone loves someone.
- (4) ? Colorless green ideas sleep furiously.

Such intuitions about the well-formedness and meaningfulness of sentences allow the linguist both to identify the class of sentences that belong to the language, i.e., the set of sentences for which a grammar must be found, and to pinpoint the grammatical and semantic features of those sentences.

Like the mathematical view, the psychological view of language takes native speaker intuitions as a central source of evidence. However, what these intuitions are evidence for is conceived somewhat differently. Recall that the Chomskyan linguist's goal is to uncover the rules and structures that constitute a speaker/hearer's actual knowledge of language. So, like the mathematical linguist, the Chomskyan linguist aims to discover a grammar for a given language, but this grammar must meet an additional constraint: it is supposed to be the grammar that speakers of the language actually know. The Chomskyan linguist seeks a grammar that is not merely **descriptively** adequate, but also **explanatorily** adequate, i.e., a grammar that speakers of the language could plausibly have learned, given their innate psychological endowment and the variety of their experiences.

To achieve the demand of explanatory adequacy, the Chomskyan linguist adopts two specific hypotheses about linguistic competence. First, a language-specific mental faculty is postulated, consisting of mechanisms that are dedicated to language production and comprehension. (Contrast this hypothesis with the view that language production and comprehension operate via the same mechanisms used for other cognitive tasks, such as contemplating a work of art or planning a trip.) The second hypothesis is that the language faculty of each child begins in a default state that contains a considerable amount of innate knowledge (called 'Universal Grammar'). (Contrast this hypothesis with the view that the child approaches language learning as a 'blank slate'.) From this state, the child is capable of learning any natural language and is 'trained' by experience to achieve a steady state that allows him or her to speak a specific language. This steady state is the mature speaker's linguistic competence.

With these hypotheses in place, the Chomskyan linguist's task is to describe both the starting state of the language faculty (i.e., the Universal Grammar) and the stable states of the language faculties of mature speakers of the various human languages. To this end, speaker/hearer intuitions constitute a vital source of evidence. Thinking about why specific constructions are not permissible has proved particularly revealing of the contours of linguistic constraints. Furthermore, cross-linguistic evidence has been invaluable for showing how patterns that look *ad hoc* in one language reflect regularities that hold across multiple languages.

At the same time, evidence going well beyond speaker/hearer intuitions has proven useful. Evidence about how language is acquired (when and in what order children use various constructions, as well as about the constructions children do not make) helps to clarify what sorts of rules children might be coming to know about their language. For example, consider the formation of questions. A rule that relies on word order, such as 'move the first verb to the front of the sentence', will not work (it's fine for 'you are happy', but it won't work for 'the woman who is walking her dog is happy'). Instead, the child must learn a rule that manipulates the underlying grammatical structure of the sentence in order to form questions correctly. And, in fact, it is observed that children do not make the errors that would suggest they are ever following the incorrect (word order-based) rule.

In a similar way, experimental work on ordinary language use and clinical investigations into linguistic pathologies (impairments to the ability to use or understand language that result from illness or injury) are becoming increasingly helpful for testing linguistic hypotheses. For example, recent work tracking hearers' eye movements has sought to illuminate such topics as the fixing of the referents of pronouns (e.g., Runner *et al.*, 2003). The idea here is that knowing where hearers look – which characters draw their eye while hearing sentences about them – provides a new window onto the syntactic hypotheses (in this case, the Binding Theory) about what pronoun referents can and cannot be. The goal is to flesh out the information gleaned from native speaker intuitions, bringing linguistic theories more closely in line with psychological hypotheses about mental processing.

The full integration of linguistics with psychology still lies some distance in the future. Nonetheless, the Chomskyan approach already imposes substantial constraints on more general psychological explanations. In particular, specifically language-dedicated processes must constitute part of the overall psychological account of the mind and the innate capacities attributed to the language faculty must eventually find explanation within the domain of evolutionary biology.

At the same time, of course, linguistic theories are themselves responsible to the constraints imposed by psychology and related fields. In principle, evidence from any quarter might prove relevant, although psychology, computational modeling, and neuroscience seem the most likely resources.

Where does this leave the mathematical and psychological views of linguistics? As mentioned above, they are certainly 'compatible' as long as one maintains that the latter is not really linguistics. From such a perspective, the constraints and goals of the psychological view are simply irrelevant to the pursuit of linguistics proper. However, there is a difficulty with maintaining such a strict separation of linguistics and psychology; namely, it requires that we be able to distinguish between linguistic facts and psychological facts. If linguistics is quite distinct from psychology, then it must be possible to delineate the mathematical linguist's abstract collection of sentences in a principled way that does not depend on psychological facts. But it is not clear that this is possible. Insofar as the mathematical linguist relies on speaker/hearer intuitions to decide which sentences belong to the language, there is an irreducible element of idealization involved in determining which intuitions count as data. Moreover, there are a range of other facts about the use of language (certain expressions are polite, whereas others are not; certain hand gestures have conventional meanings; poetry often employs words in unusual ways) and it is not clear what principles might allow the mathematical view to identify which (if any) of these facts are among the linguistic ones (see Fodor, 1981 and Antony, 2003 for discussion). As a result, the mathematical view risks relying on mere stipulation, whereas the psychological view is able to identify the linguistic facts through empirical investigation as those facts that are explained by the functioning of the language faculty.

This sharp distinction between the mathematical and psychological views is not mandatory, however. One can individuate some of the mathematical view's languages (i.e., its abstract sets of sentences) precisely by reference to the linguistic competence of (idealized) native speakers in specific linguistic communities: a certain abstract language *L* is the language spoken by speaker *S* in virtue of *S*'s linguistic competence. In this way, the powerful logical and model-theoretic tools of the mathematical linguist can be brought to bear on language *L* in some independence from the considerations of the psychological view. Difficult questions remain about the extent to which a grammar produced in this way needs to cohere with results from psychological and other

empirical research. But viewing the mathematical and psychological views as connected to this extent allows the science of linguistics to proceed in multiple directions at once, unconstrained by *a priori* restrictions on either its methods or its evidence.

Plato and His Predecessors

Predecessors

The first attempts at explicit theorizing about language in ancient Greece occurred among the itinerant teachers known as the Sophists (late 5th century B.C.E.). Ideas about language are, however, at least implicit in some texts prior to this. Parmenides (late 6th–mid-5th century B.C.E.) famously declared the impossibility of speaking or thinking of what is not, which seems to presuppose a view of meaning as consisting in, or at least requiring, reference to something in the world. And a generation or so earlier Heraclitus drew attention to the seeming paradox that one of the words for a bow, a deadly weapon, was *bios*, which is identical in spelling with the Greek word for ‘life’ (DK 22B48). This remark appears to trade on the notion that one would expect a certain fitness between words and their objects. And a similar notion is apparent in the etymologizing that occurs periodically in Homer and Hesiod; for instance, Odysseus was named by his grandfather, who was angry (*odussamenos*) towards many (*Od.* 19.407), and also himself suffers the effects of the gods’ anger (*Od.* 1.62).

It is, though, in the Sophistic period that language first becomes the object of sustained reflection. Several texts from this period address the question of the origins of language, sometimes in the context of a broader account of the origins of society. A consistent picture emerging from these texts is that language was devised by humans themselves, in response to the needs of early communities. It came into being through a set of decisions about what names should apply to what objects, and in that sense is conventional rather than natural. These decisions were not necessarily seen as entirely arbitrary; the Sophist Protagoras, in Plato’s dialogue of that name (322a6), speaks of language as the product of a *technê*, ‘skill,’ analogous to building or agriculture – which implies that one set of names may be better crafted (whatever that means) than another. But still, according to this view, there were clearly many different possible and acceptable sets of names. The picture is hardly sophisticated. However, it is the first attempt in Greek thought to understand, in something like the spirit of a social scientist – as opposed, say, to appealing to divine fiat – how language could have come about.

The question of constraints on the naming of objects was further pursued by the Sophists in a field of inquiry known as *orthotês onomatôn*, ‘correctness of names.’ It is hard to reconstruct

precisely what this involved, but it seems to have been concerned, in some sense, with making the fit between words and the world as good as possible; it thus shares something with the pretheoretical concerns implied by Homer and Heraclitus. Two Sophists, Protagoras and Prodicus, were especially associated with this subject. Protagoras is said to have distinguished the grammatical genders of words, and to have been willing to criticize existing genders of words as not appropriate to the nature of their objects; *pêlêx* ‘helmet,’ for example, should be masculine, not feminine. He also drew distinctions among what would now be called speech acts – entreaty, question, answer, and command – and was again ready to correct people’s choices among these modes of discourse. Prodicus, on the other hand, was especially concerned with precise definitions of words, including precise distinctions among nearly synonymous words; reports (and parodies) of this are common in Plato and elsewhere.

Despite Protagoras’s anticipation of the notion of speech acts, the overriding conception of language in this period was as consisting purely of names applying to objects. And this led to some extraordinary claims about language. Several Sophists and their contemporaries are reported to have argued that falsehood is impossible, that there is no such thing as contradiction, or both. The essential point of these arguments is that there are only two possible options: to speak the truth or not to speak at all. The connection with the naming conception of language is clear. If all language does is name, then truth can only consist of successfully naming an object or state of affairs. But in that case, there is no prospect of successfully *referring* to something, yet saying something false *about* it, or of two people successfully referring to the same object, yet saying contradictory things about it. The only alternative to successful naming – that is, truth – on this conception is unsuccessful naming; but if naming is all language does, unsuccessful naming is not genuine language at all.

One other text from this era deserves mention. The Sophist Gorgias wrote a treatise entitled *On What Is Not* (*Peri tou mê ontos*), in which, again, extraordinary conclusions were argued for, namely: (1) there is nothing, (2) even if there were anything, it could not be known about, and (3) even if it could be known about, this knowledge could not be communicated to anyone else. There is much dispute about the purpose of this production, although Parmenides is clearly in some way the target. But the third part, on the impossibility of communication, is of particular interest for the study of language. The

main arguments in this part were, first, that words are wholly different types of entity from the objects that they name, and second, that the contents of any two people's minds are necessarily different. We need not suppose that Gorgias actually *believed* communication was impossible. However, it is clear that he was raising (without attempting to answer) the deep question of how words manage to refer to objects at all.

Plato

The Sophists' ideas on language form the context for the reflections on this subject by Plato (mid-420s–347 B.C.E.). In a number of dialogues, widely (though by no means universally) regarded as from early in Plato's career, Socrates and his interlocutors are shown trying to answer questions of the form "What is F?", where F stands for some significant ethical characteristic such as courage, piety, or virtue in general. This enterprise is not fundamentally linguistic; even though it is often described as a search for definitions, Socrates is not interested primarily in the meanings of terms, but in the real natures of the items that those terms refer to. Nonetheless, the search is understood to require sensitivity to how the terms in question are actually used, and in this respect it seems to owe something to Prodicus's interest in precise distinctions of meaning. Socrates in these dialogues occasionally professes allegiance to Prodicus; the professions are never entirely serious, but they are not without some basis in his actual procedure.

Plato takes up the issue of correctness of names in his dialogue *Cratylus*. Here Socrates is made to examine two opposing (and extreme) views. One view, that of Hermogenes, is that linguistic correctness is purely a matter of convention. Indeed, Hermogenes even ignores the connotations of society-wide agreement normally present in the word 'convention' (*nomos*), suggesting that each individual is free to use words in whatever manner he or she decides. Against this, Socrates argues that if one accepts a view of reality as fixed – to which Hermogenes readily assents – one cannot regard correctness in language as a matter of merely arbitrary choice. Cratylus, on the other hand, holds the view that some names are *naturally* correct and some are not; the correct ones fit the nature of the things they refer to, while the incorrect ones do not. A trivial example is that 'Hermogenes' is not Hermogenes' true name, because he is not in fact the son of the god Hermes. But it is of course a much more difficult question what, in general, the natural fitness of names might consist in. The view explored by Socrates and Cratylus is that most names can be analyzed etymologically into a small number of 'primary names,' and that these primary names are correct in virtue of a natural resemblance

between their sounds and their objects. It is not clear how far Plato means us to be attracted by this theory. Socrates finds much to admire in it. But he argues that a role for convention in language cannot be altogether excluded. He is also dissatisfied with the fact that, in the version of the theory promoted by Cratylus, the originators of these names were Heracliteans who held that everything was in a state of constant change – a view that he, Socrates, cannot accept. Whatever we are ultimately supposed to think about the theory, however, the examination of the purported etymologies occupies a large proportion of the dialogue, suggesting that Plato thinks it deserves very serious consideration. Given the history of etymologizing mentioned earlier – a history to which the discussion seems sometimes to allude – this is perhaps not surprising, however frustrating and alien this portion of the dialogue may seem to us.

Another significant point that Socrates makes in *Cratylus* is that an understanding of things is more important than, and indeed indispensable for, the optimal naming of those things. And, as *Cratylus* and other dialogues make clear, the most important things, in the mature Platonic conception, are the unchanging, purely intelligible Forms – entities such as Beauty itself or Goodness itself, as opposed to any of the particular items we might call beautiful or good. Now these Forms are not, of course, linguistic entities. But it is plausible to suppose that one of the reasons Plato had for believing in Forms was a linguistic reason. Given the difficulty of the Socratic search for answers to "What is F?" questions about the virtues, it is natural to wonder how we manage to understand and use terms such as 'piety,' 'courage,' or 'virtue' at all. Even though we seem to have no difficulty employing these terms in ordinary discourse, Socrates's attempts to pin down what exactly they refer to consistently end in failure. It might well have seemed an attractive solution to this puzzle to suppose that our understanding of such terms derives from our (no doubt incomplete) grasp of the corresponding Forms, which are only imperfectly exemplified in the world around us; if Forms are what the terms really refer to, then the Socratic search, focused as it is on ordinary instances, is bound to fail. Of course, the project of understanding the Forms is hardly less ambitious, as Plato readily concedes.

Plato also tackles the question of how falsehood (along with contradiction) is possible. And here he makes what should be considered a definitive breakthrough. In the *Theaetetus* the characters are shown struggling unsuccessfully with the question of how false judgment is possible. Socrates also proposes a model of language that involves names being 'woven together' into an 'account' (*logos*,

202b), and this seems to promise an advance beyond the Sophistic conception of language as doing nothing but naming. But the promise is not fulfilled; no linguistic items are recognized other than names, and the implications of structure present in the notion of a 'weaving together' (*sumplokê*) are not followed through. In the *Sophist*, however, Plato has the central character (a visitor from Parmenides's hometown, Elea) draw a crucial distinction between a name (*onoma*) and a 'thing said' (*rêma*): the name identifies the thing being spoken of, and the 'thing said' delivers information about it. Once this distinction is in place, it is easy to see how both true and false statements may be made about the same objects. The dialogue involves much broader discussion about the legitimacy of thinking or speaking of what is not; and the term 'speaking of what is not' regularly refers, among other things, to the speaking of falsehoods. But once the possibility of this is established (against Parmenides) in general terms, the specifically linguistic details of how falsehood is possible are established relatively quickly. The importance of moving beyond the naming conception of language can hardly be overestimated; until it was clearly understood that language does more than just naming, the study of grammar, syntax, or anything else to do with the structure of language was out of the question.

Plato's *Cratylus* and Its Legacy

J E Joseph, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Plato's *Cratylus* is the first complete surviving philosophical inquiry into the arbitrariness of language, and arguably the greatest. Although it was long thought to have been an early work of Plato's on account of being 'merely' about language, heightened appreciation of its importance over recent decades has prompted scholars to redate it to his 'great' middle period. It takes the form of a debate among three of Plato's teachers, Cratylus, Hermogenes, and Socrates, about the correctness of words (the subject taught by Cratylus). Cratylus and Hermogenes are

arguing the question within the Sophists' staple pedagogical dichotomy of *physis* 'nature' versus *nomos* 'convention.' Socrates joins them, and they invite him to adjudicate as to who is right: Cratylus, who holds that a word is correct only if naturally connected to its meaning, or Hermogenes, who thinks that any word can designate anything just as well as any other.

They begin by considering proper names, which seem obviously conventional since chosen willfully for individuals, usually by their parents – although, significantly, Plato had changed his own name (originally Aristocles) – and then proceed to common nouns, the choice of which is lost in prehistory. In both cases, Hermogenes takes the conventionalist

view and Cratylus the naturalist one. But Cratylus sounds absurd in the proper-name context when he holds that Hermogenes isn't really his interlocutor's name because he isn't actually 'born of Hermes' (which would imply that he is lucky and eloquent, when in fact he is neither). And Hermogenes sounds equally absurd in the common-noun context when he holds that it would make no difference if someone referred to a man as 'horse' and to a horse as 'man.'

Socrates raises the objection that, were this latter argument the case, there would be no way of distinguishing truth from falsehood, a position taken by relativists like Protagoras but anathema to Socrates (and Plato), for whom things have a natural reality of their own that does not depend on the perception of individuals. Socrates lays out the characteristically Platonic view that the things we perceive in the world around us are not really 'real,' in the sense that they are not permanent but in flux, are not the wholes we perceive but conglomerations of atoms, and are not perceived in the same way by all of us. The table at which I am now writing was not a table 30 years ago but has been made up from what was then parts of trees, which themselves did not exist 100 years ago, and in time the table will burn or decay, its substance taking on yet another form. The meaning of the word *table*, the knowledge I have of what a 'table' is, is not this transient thing. On the contrary, actual tables are made in accordance with the *function* of a table, which requires it to have a particular shape, that of a flat top surface supported by legs.

This is what Plato calls the *idea* of a table, what defines the *ideal form* of a table. That ideal form is the true, unchanging reality. Any individual table is merely an attempt to realize that ideal form in transient matter. The meaning of the word *table* is that idea, not any particular material instantiation of it. Moreover, ideas are all that we can 'know,' since knowledge must be of permanent, unchanging things, as opposed to the perception or opinion we can have of material things. We may disagree over whether a particular table is beautiful, but we cannot *know* that it is or is not beautiful in the same way that we can know what a table is and what beauty is – although, actually, such knowledge is not accessible to just anyone. The Ideal Forms inhabit a heaven into which only the philosopher, the wisest of men, can see (hence the political stance of Plato's *Republic*, where the ideal ruler is the philosopher-king).

From this point on, Socrates directs all his questions to Hermogenes, with Cratylus silent until quite late in the dialogue. In response to Socrates's point about truth, Hermogenes raises a powerful objection: If truth depends on some kind of natural relationship between word and thing, how is it possible for

different languages to exist? Socrates does not attempt to answer this directly (a sign of how seriously Plato took the question), but steers the dialogue off in the direction that the question demands. He asks Hermogenes about the purpose of words, and they conclude that words exist for two reasons: to discriminate among things, i.e., to pick out their *ousia*, the true essence that belongs to them alone; and to transmit that knowledge from the few who can perceive it directly to the many who cannot.

This leads Socrates to ask about the origins of the words we use, paving the way to the etymological inquiry that will form the great central bulk of the dialogue. Etymology, which in Greek means the 'study of truth,' was one of the 'sciences' based on language in which instruction was offered by Socrates's contemporaries the Sophists. The most successful and widely sought after of these was rhetoric, the art of using language in order to persuade, persuasion being the ultimate political commodity in the democracy of Athens. Just as they had no faith in democracy, Socrates and Plato disdained rhetoric as mere word-play, not at all concerned with real knowledge. Etymology, however, had more of an appeal. It not only claimed to be the study of truth, but did offer real insights into what words meant in an earlier time, closer to the moment of their creation. The great question, Socrates says, is whether whoever made the words we use – the semimythical *nomothetes*, which also means 'lawgiver' – really perceived the true essence of the thing he was naming, and if so, whether he succeeded in the word maker's craft of *mimesis*, 'imitation' of that essence in the sounds of language. This provides, in theory at least, the answer to Hermogenes's question about how it is possible for different languages to exist unless words are purely conventional: any number of 'correct' words are conceivable to designate a given meaning as long as they capture its essence and make it plain.

As Socrates proceeds through various classes of words and their etymologies, the thesis emerges that the creation of the Greek lexicon took place under the influence of Heraclitus's doctrine that 'everything flows.' Accounts are given whereby words of a positive moral sense are traced back to roots and sounds indicating motion, while those of a negative moral sense have roots expressing immobility. But all sorts of problems ensue. Socrates points out how easy it is, when no such account suggests itself, to have recourse to some *ad hoc* explanation, such as attributing a word to foreign origin. When it comes to *mimesis*, he notes that *r*, a trilled consonant in Greek, seems naturally to denote motion by the very way it is produced, and indeed appears in many

of the words with positive qualities that he traces back to the idea of motion – yet it does not appear in the word for ‘motion’ itself, *kinesis*. Socrates also cites cases of words known to have undergone sound change, which he puts down to people who “care nothing about the truth, only about how they shape their mouths.” This is a swipe not just at the *hoi polloi* in general but especially at rhetoricians and the poets who along with them are banned from Plato’s ideal Republic.

He finally turns back to Cratylus to discuss another fundamental problem with words being naturally connected to their meaning. Cratylus has insisted that the meaning of a ‘correct’ word must not only be embodied directly in the sounds of the word but also be indistinguishable from the idea of what it designates. Socrates leads him to admit that this is not in fact the nature of mimesis – if the image of something were identical to that something, it would not be an image at all but would actually have become the thing itself. Instead, the art of mimesis in language is to capture and reproduce some part of the essence of things; indeed, Socrates affirms, it is precisely in this way that a language *should* be constructed and used. But he admits, once constructed, the language passes into the hands of the many, who care only about the ‘vulgar’ function of communicating with their fellows, for which conventional words (not ‘correct’ ones in Cratylus’s sense) suffice. The investigation reaches an impasse, and Socrates concludes by opining that the Greek language really was created under the Heraclitean philosophy, but that the philosophy itself is misguided; that the lawgiver did not consistently embody its principles in sound; and that, even when he did so, words have subsequently undergone change at the hands of the mob, who care only about communication and sounding nice.

As a result, the dialogue ends up rejecting the possibility that the study of language opens a path to understanding the true nature of the universe. For each word, one would first have to decide whether it was created with an eye to truth, whether that truth was properly and consistently imitated in sounds, and whether the original form of the sounds has remained unaltered. But the first of these decisions already demands that we know what the truth is independently of the word in question – and if we can do that, there is no point inquiring further. This is clearly disappointing to Socrates, who believes that words should be naturally and deterministically bound to their meanings, but he is forced to admit that, at least as they are used for the vulgar purpose of communication, they are not in fact so bound. The way to knowledge of the truth is not therefore through the

study of etymology but through the kind of dialectic inquiry that the *Cratylus* itself embodies.

This is a blinding condemnation of the futility of any language-based ‘science.’ Yet so intense and sustained is Socrates’s attempt to disprove Hermogenes’s conventionalist stance through an examination of the hidden etymological structure of words that, although his attempt is ultimately given up as unsuccessful, the dialogue nevertheless has been read for centuries as a detailed study of Greek etymology. It was even interpreted as coming down on the side of Cratylus, holding that language really is grounded in nature, when in fact it makes clear that the positions taken by both Cratylus and Hermogenes are unsustainable in isolation from one another and from deeper inquiry into the nature of word making and mimesis.

The misinterpretations are less surprising when one considers how powerful and universal is the impulse to interpret language as having a meaning far deeper than what appears on the surface. This is nowhere more true than in European culture, formed by the doctrine of a god who is Himself *logos*, the Word, the language-based and language-like intelligence that created the world and continues to order it. From medieval through modern linguistic thought we find various attempts at containing arbitrariness, for instance, by locating it in nouns only, as opposed to verbs and other more ‘functional’ parts of speech; in the lexicon as a whole, as opposed to grammar; in conventional signs, which are imagined as having come about as an accretion onto more original and basic ‘natural’ signs; in a ‘universal’ grammar that underlies all languages, which differ from one another only in relatively superficial particulars.

Modern secular culture has not given up its faith in language but rather has problematized and debated its centrality in various guises that can be read as reworkings of the problem outlined and investigated in the *Cratylus*. Modern linguistics is predicated upon the belief in something deeper than the actual words we speak and hear, wherein their *real* structure lies, and perhaps also their real meaning. We find this impulse in Humboldt’s *energeia*, in Jakobson’s functionalism, in Chomsky’s universalism, and in various attempts to portray thought as conditioned by meaning, including the Sapir–Whorf hypothesis at the micro level of words, and the regimes of language described by present-day linguistic anthropologists and discourse analysts (in the wake of Nietzsche and Foucault) at the macro level of discourse. Even Saussure, with whom the modern doctrine of the arbitrariness of linguistic signs is most closely associated, taught that everything having to do with the systematic nature of languages – and languages

are entirely systematic by his account – needs to be approached from the point of view of limiting the arbitrary.

The legacy of the *Cratylus* has yet to play itself out. Once linguists manage to confront the powerful challenge it puts to the whole enterprise, we can perhaps begin to approach an understanding of language complex enough to take account of how Hermogenes, Cratylus, and Socrates are actually each right and wrong, and then to formulate, for the first time, new questions that actually pass beyond the concerns of the ancient dialogue rather than endlessly recycling them.

Plurality

P Lasersohn, University of Illinois at Urbana-Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Plural expressions may be intuitively characterized as those involving reference to multiple objects. Semantic theories differ, however, in how this intuition is worked out formally.

The most popular approach is to treat plural expressions as referring to some sort of 'plural object,' or group. That is, alongside individual objects such as people, tables, chairs, etc., we assume there are groups of such objects, and that plural expressions refer to these groups in much the same way as singular expressions refer to individuals. Just as singular noun phrases denote and quantify over individuals, plural noun phrases denote and quantify over groups; just as singular predicates hold true or false of individuals, plural predicates hold true or false of groups.

An alternative, advanced by Schein (1993) (building on earlier logical work by George Boolos) is to regard a plural term as denoting each of several individuals directly, rather than denoting the group containing these individuals. This gives the effect of treating denotation for plural terms as a relation rather than a function; it is the denoting relation itself, rather than the denoted object, which is plural. The primary advantage of this technique is that it allows a reasonable treatment of noun phrases such as *the sets that do not contain themselves*, which potentially give rise to Russell's paradox in more conventional treatments.

Among analyses that do regard plural expressions as referring to groups, the main options are to identify groups with *sets*, or with *mereological sums*. The latter choice is favored especially by those who regard sets as abstract, mathematical objects existing outside of space and time. As Link (1998) puts it, "If my kids turn the living room into a mess I find it hard to believe that a set has been at work." However, not all authors share the intuition that sets of concrete objects are themselves abstract, and in any case the issue seems more philosophical than linguistic (but see the discussion of conjoined noun phrases below).

No matter which approach is adopted, a central problem in the semantics of plurality is determining the range and distribution of readings available to sentences containing plural expressions. Sentence (1a), for example, is intuitively interpreted as predicating the property of being numerous to our problems *collectively*; no individual problem can be numerous. Sentence (1b), in contrast, requires all (or nearly all) the individual children to be asleep; the predicate applies *distributively*. Sentence (1c) seems ambiguous between collective and distributive readings, meaning either that the T.A.s together earned exactly \$20 000, or that they each did:

- (1a) Our problems are numerous.
- (1b) The children are asleep.
- (1c) The T.A.s earned exactly \$20 000.

Such examples raise several issues: Are plural expressions authentically ambiguous between collective and distributive readings, or are both interpretations covered under a single, very general meaning?

If there is an authentic ambiguity, is it a simple two-way ambiguity between collective and distributive readings, or are there other possibilities? What is the locus of the ambiguity: in the noun phrase, the predicate, or both?

In favor of the view that there is an authentic ambiguity, consider a situation in which there are two T.A.s, and each of them earned exactly \$10 000. In this case, sentence (1c) is true. Sentence (2) is also true in this situation:

- (2) The T.A.s earned exactly \$10 000.

This suggests that there are two distinct figures, both of which are the exact amount the T.A.s earned: in one sense they earned \$20 000, and in another sense they earned \$10 000 – but this appeal to multiple senses amounts to a claim of ambiguity.

An ambiguity is also suggested by patterns of anaphora, as argued by Roberts (1991). Sentence (3a) allows the continuation in (3b) if (3a) is interpreted as predicating $\lambda x \exists y [\text{piano}(y) \ \& \ \text{lift}(x, y)]$ of the group of students as a whole, but not if this predicate is understood as applying to each student separately. (A third interpretation, in which there is some piano y such that the predicate *lifted* y applies to the individual students, also allows the continuation in (3b), but this does not affect the argument.)

- (3a) The students lifted a piano.
(3b) It was heavy.

If sentence (3a) is unambiguous, with no formal differentiation between the collective and distributive interpretations, it is hard to see how we could capture this difference in anaphoric potential.

If there is an ambiguity, one may ask whether the fully collective and fully distributive readings are the only ones available, or if instead there may be ‘intermediate’ readings. Intermediate readings appear to be called for in examples like (4):

- (4) The shoes cost \$75.

This sentence is most naturally interpreted as meaning that each pair of shoes costs \$75, not that each individual shoe costs that much, or that all the shoes together cost that much.

Gillon (1987) argues that sentences with plural subjects have as many readings as there are *minimal covers* of the set denoted by the subject noun phrase, in which a *cover* of a set A is a set C of nonempty subsets of A such that their union, $\cup C$, is equal to A , and a cover of A is *minimal* iff it has no subsets that are also covers of A ; this idea is developed further by Schwarzschild (1996) and others. Under this proposal, the pragmatic context makes a particular cover salient, and the predicate is required to hold of each

element of the cover. The fully distributive and fully collective readings reemerge as special cases.

However, cover-based analyses face a challenge in dealing with examples like (1c): Suppose John, Mary, and Bill are the T.A.s, and each of them earned \$10 000. In this case, the predicate *earned exactly* \$20 000 holds of each cell of the cover $\{\{\text{John, Mary}\}, \{\text{John, Bill}\}\}$, but sentence (1c) is not intuitively true in this situation.

Whether it appeals to covers or not, an ambiguity analysis must address the issue of where in the sentence the ambiguity is located. Early treatments often seemed to take for granted that it was the plural noun phrases themselves which are ambiguous, but many more recent treatments trace the ambiguity to the predicates with which the noun phrases combine (Scha, 1984; Dowty, 1986; Roberts, 1991; Lasersohn, 1995). A standard argument for this view comes from examples like (5):

- (5) The students met in the bar and had a beer.

The natural interpretation is that the students met collectively but had separate beers. This reading is easily obtained if we treat the subject noun phrase as unambiguously denoting the group of students as a whole, and treat the conjunct verb phrases as predicates of groups, with the distributive predicate *had a beer* holding of a group iff each of its individual members had a beer; the denotation of the whole, coordinate verb phrase may then be obtained by intersection. If we try to claim that the collective/distributive ambiguity is located in the subject noun phrase, however, it seems impossible to give a consistent answer as to which reading it takes in this example.

A suitable ambiguity in the predicate may be obtained by positing an implicit operator on the predicate. Link (1998) and Roberts (1987) suggest an optional operator on the verb phrase, notated “ D ”, and interpreted as $\lambda P \lambda x \exists y [y \Pi x \rightarrow P(y)]$, where Π is the relation an individual stands in to the larger groups of which it forms a part. This gives a simple two-way ambiguity, depending on whether the operator is present or not; intermediate readings may be obtained using a more complex operator which quantifies over elements of a cover (Schwarzschild, 1996). Either operator is easily generalized across types to give distributive readings for non-subject argument places (Lasersohn, 1998).

It should be noted that the lexical semantics of some predicates prevent them from participating in the collective/distributive ambiguity: a verb like *sleep*, for example, cannot apply to a group without also applying to the individual members of the group. Adding a distributivity operator in this case is redundant, and does not result in a difference in meaning.

Conversely, certain predicates apply only to groups: *gather*, for example. Such predicates do show collective/distributive ambiguities however, when applied to arguments denoting groups of groups:

- (6) The tribes gathered.

Example (6) may be used to mean that each tribe gathered separately, or that all the tribes gathered together.

A good deal of work has been devoted to the relation between *conjunction* and plurality (Link, 1998; Hoeksema, 1983; Landman, 1989a; Lasersohn, 1995; Schwarzschild, 1996; Winter, 2001) because conjoined noun phrases sometimes admit collective readings, as in (7):

- (7) John and Mary lifted the piano.

Such examples suggest that coordinate noun phrases may denote groups in much the same fashion as plural noun phrases. Such sentences also admit a distributive reading, which may be obtained either through the use of a distributivity operator as with other plural noun phrases, or by reducing the coordination to propositional conjunction, via a generalized conjunction operator or conjunction reduction transformation.

Conjoined noun phrases have sometimes been used to argue that semantic theory must allow reference to *higher-order groups* (Hoeksema, 1983; Landman, 1989a). This is easily accomplished in set theory, since sets may contain other sets as members: $\{a, \{b, c\}\} \neq \{\{a, b\}, c\} \neq \{a, b, c\}$, but is less straightforward if groups are modeled as mereological sums.

- (8a) Blücher and Wellington and Napoleon fought
against each other at Waterloo.
(8b) The cards below seven and the cards from seven
up are separated.

Example (8a), from Hoeksema (1983), may be parsed in either of two ways: $[[\text{Blücher and Wellington}] \text{ and } [\text{Napoleon}]]$ or $[[\text{Blücher and } [\text{Wellington and Napoleon}]]]$. It is intuitively true relative to the first parse but false relative to the second, suggesting that the two parses correspond to denotations such as $\{\{b, w\}, n\}$ and $\{b, \{w, n\}\}$. Likewise example (8b), from Landman (1989a), is not equivalent to *The cards below 10 and the cards from 10 up are separated*. But if reference to higher-order groups is disallowed, the subject noun phrases of these two sentences would seem to refer to the same group, namely the group containing all the individual cards as members. The opposing view that noun phrases need never refer to higher-order groups has been defended in detail by Schwarzschild (1996), who points out that the pragmatic context may make

salient a particular division of the denotation into subgroups even if that denotation is first-order; correct truth conditions may be obtained if the semantics is sensitive to this pragmatically supplied division.

A number of additional issues arise in the semantics of plurality, which can only briefly be mentioned here: Certain *adverbs*, such as *together* or *separately*, seem to force a collective or distributive reading, but the exact mechanism by which they do this is a matter of some dispute (Lasersohn, 1995; Schwarzschild, 1994; Moltmann, 1997). Plural expressions share a number of characteristics with *mass terms*, suggesting a unified analysis (Link, 1998). Plural noun phrases affect the *aspectual class* of predicates with which they combine, suggesting a parallel in the domain of *events* to the structure of groups among individuals (Krifka, 1989) – a parallel also suggested by the phenomenon of *verbal plurality* or ‘pluractionality’ (Lasersohn, 1995). Finally, the interpretation of *bare plurals*, or plural noun phrases with no overt determiner, and particularly the alternation between the *existential*, *generic*, and *kind-level* readings, illustrated in (9), has attracted enormous attention; but much of this work belongs more properly to the study of genericity and indefiniteness than to the semantics of plurality *per se* (Carlson, 1980; Carlson and Pelletier, 1995).

- (9a) Raccoons are stealing my corn.
(9b) Raccoons are sneaky.
(9c) Raccoons are widespread.

Polysemy and Homonymy

A Koskela and M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Polysemy and homonymy both involve the association of a particular linguistic form with multiple meanings, thus giving rise to **lexical ambiguity**.

Polysemy is rooted in a variety of semantic-pragmatic processes or relations through which meanings of words extend or shift so that a single lexical item (a **polyseme**) has several distinct senses. For example, *language* is **polysemous** in that it can be used to refer to the human linguistic capacity (*Language evolved gradually*) or to a particular grammar and lexis (*Learn a new language!*). The most clear-cut cases of polysemy (versus homonymy) involve **systematic** (or **regular**) **polysemy** (Apresjan, 1974), in which the relation between the senses is predictable in that any word of a particular semantic class potentially has the same variety of meanings. For example, words for openable coverings of apertures in built structures (*She rested against the door/gate/window*) are also used to refer to the aperture itself (*Go through the door/gate/window*). In **non-systematic** polysemy, the word’s two senses are semantically related, but are not part of a larger pattern, as for *arm* of government versus human *arm*. Within the literature, theoretical considerations often lead authors to use *polysemy* to refer only to either systematic or non-systematic polysemy, and so the term must be approached with caution.

Homonyms, in contrast, are distinct lexemes that happen to share the same form. They arise either accidentally through phonological change or lexical

borrowing, or through some semantic or morphological drift such that a previously polysemous form is no longer perceived as being ‘the same word’ in all its senses. *Tattoo*₁ ‘an ink drawing in the skin’ and *tattoo*₂ ‘a military drum signal calling soldiers back to their quarters’ provide a clear example of homonymy, in that the two words derive respectively from Polynesian *ta-tau* and Dutch *taptoe* ‘turn off the tap’ (which was also used idiomatically to mean ‘to stop’). The formal identity of homonyms can involve both the phonological and the written form, as for *tattoo*. **Homophones** need only be pronounced the same, as in *tail* and *tale*, and **homographs** share written form, but not necessarily phonological form, as in *wind* /wind/ and *wind* /waɪnd/. Homographs that are not homophones are also called **heteronyms**.

Polysemy and homonymy are generally differentiated in terms of whether the meanings are related or not: while polysemous lexical items involve a number of related meanings, homonyms, as accidentally similar words, do not have any semantic relation to each other. However, as discussed below, a clear distinction between polysemous and homonymous items remains difficult to draw. Nevertheless, the need to distinguish between them remains. For lexicographers, the distinction generally determines how many entries a dictionary has – homonyms are treated as multiple entries, but all of a polyseme’s senses are treated in one entry. For semanticists wishing to discover constraints on or processes resulting in polysemy, weeding out the homonymous cases is necessary. For those wishing to model the mental representation of lexical knowledge, the issue of semantic (un)relatedness is similarly important.

Another definitional issue concerns the distinction between polysemy and **vagueness**, in which a lexical item has only one general sense. (Some authors refer to this as **monosemy**.) This raises the question of how different two usages of the same form need to be to count as distinct polysemous senses rather than different instantiations of a single underlying sense. For example, the word *cousin* can refer to either a male or a female, but most speakers (and linguists) would not view *cousin* as having distinct ‘male cousin’ and ‘female cousin’ senses. Instead, we regard it as vague with respect to gender. A number of different methodologies and criteria have been used to draw the line between polysemy and vagueness, but these are not uncontroversial. The distinction is also influenced by theoretical assumptions about the nature of lexical meaning; thus, demarcation of senses is one of the more controversial issues in lexical semantics.

Evidence Used in Differentiating Homonyms and Polysemes

The kinds of evidence used for differentiating polysemous and homonymous items can be roughly divided into two types: evidence regarding the relatedness of the meanings involved and evidence regarding any formal (morphosyntactic or phonological) differences in the linguistic form that correspond to the distinct senses.

The key principle for distinguishing polysemes and homonyms involves the relatedness of the meanings associated with the linguistic form: unrelated meanings indicate homonymy whereas related meanings imply polysemy. Relatedness can either be determined diachronically by establishing if the senses have a common historical origin, or synchronically – and neither method is unproblematic. The simplest criterion for synchronic relatedness is whether or not the senses participate in the same semantic field. On this criterion, metonymically related senses such as *bench* ‘place where the judge sits’ and ‘the judge’ are polysemous, but metaphorically related senses such as *foot* ‘body part’ and ‘bed part’ are not. Nevertheless, the two senses of *foot* here are usually considered to represent polysemy, as the more usual methodology for determining synchronic relatedness involves individuals’ intuitions. Intuitive judgements of semantic relations are, however, always subjective, and it may be questioned whether people’s metalinguistic reasoning about meaning relations can reflect how lexical meaning is mentally represented. Historical evidence has in its favor the fact that etymological relations are often less equivocal; but many approaches consider such evidence irrelevant to

questions of mental representation, as etymological information is not part of most speakers’ competence. Furthermore, diachronic and synchronic evidence can be contradictory. In some cases, despite the fact that the different senses are etymologically related, native speakers today perceive no semantic relation. Such is the case with the classic homonym *bank*; the two senses ‘financial institution’ and ‘a raised ridge of ground’ can be traced back to the same proto-Germanic origin. There are also instances where at least some speakers perceive a synchronic relation in words with no shared history. For example, *ear* ‘hearing organ’ and *ear (of corn)* are perceived by some speakers to be metaphorically related, analogous to other body-part metaphors, but in fact they have separate sources.

Formal criteria are also used to distinguish homonymy and polysemy. One criterion, adopted widely in lexicography, is that polysemous senses should belong to the same grammatical category. Thus, noun and verb senses of words such as *waltz*, derived through zero derivation (conversion), might be considered distinct lexical items, and therefore homonyms. Similarly, the potential for different plural forms for the meanings of *mouse*, ‘small rodent’ and ‘a computer input device’ (*mice* and *mouses*, respectively), could indicate that the distinct senses reflect distinct homonymous lexemes. However, the formal criterion often conflicts with the semantic criteria. One can easily see the semantic connection between *waltz* (n.) and *waltz* (v.) as part of a pattern of regular polysemy (where any noun denoting a type of dance can also be a verb meaning ‘to perform that dance’), and most people appreciate the metaphorical connection between the two types of *mouse*. But for some approaches to the lexicon, any morphological differences associated with different senses of the form force its treatment as a homonym, resulting in etymologically related homonyms. The contradictions of the formal, diachronic, and synchronic semantic criteria have led some to abandon strict distinctions between homonyms, polysemes, and vague lexemes. Tuggy (1993) proposes a continuum between these categories, which relies on variable strengths of association among meanings and forms.

Theoretical Approaches to Polysemy and Homonymy

While we have so far attempted a theory-neutral definition and description of polysemy and homonymy, variability in the interpretation of these terms is often at the heart of the contrasts among theoretical approaches. The approach is often determined by the

range of phenomena considered (and *vice versa*) – for instance some models define *polysemy* as equivalent to *systematic polysemy* and treat irregular cases as tantamount to homonymy.

In early generative theory, attempts were made to treat polysemy as the product of synchronic derivational processes. The lexical representation of a word would include a meaning, and further meanings could be derived via lexical rules that operate on some semantic class of words (e.g., McCawley, 1968; Leech, 1974). Leech (1974) notes that such rules are limited in their productivity, and can be seen as motivating but not predicting new senses of words. The assumption of a basic meaning from which additional meanings are derived continues as a theme in some **pragmatic** approaches to polysemy. For instance, Nunberg (1978) posits that words have lexical meanings but that they can be used to refer in various ways based on a number of conventional referring functions that allow language users to effect different sense extensions. Thus, a referring function that relates producers with their products predicts the interpretation of *Chomsky* (primary reference is to a person) as ‘the works of Chomsky’ in *Chomsky is hard to read*. Other theorists have taken the position that word meaning is radically underspecified in the lexicon (e.g., Bierwisch, 1983) or extremely general in sense (Ruhl, 1989) and that semantic or pragmatic factors allow for more specific interpretations in context. Such an approach is Blutner’s (1998) *Lexical Pragmatics*, where lexical meaning is highly underspecified. Meanings are enriched by a pragmatic mechanism that specifies which particular concepts the word refers to in a particular use based on contextual factors. Such approaches erase the distinction between polysemy and vagueness.

The **generative lexicon** (Pustejovsky, 1995) is an approach to lexical semantics that emerges from computational linguistic work. Sense disambiguation presents a key challenge for natural language processing and drives much current polysemy research. In this theory, systematic polysemy is generated by lexical rules of composition that operate on semantic components specified in the representation of lexical items (and so it could be seen as a development from the early generative approaches). The main concern is to account for regular types of meaning alternation (such as the aperture-covering alternation of *door* and adjectival meaning variation, as in *fast car*, *fast typist*, *fast decision*, *fast road*, etc.) in a manner that avoids the problems of simple enumeration of word senses in the lexicon and explicates the systematic nature of meaning variation in relation to the syntagmatic linguistic environment. The meaning variation of *fast*,

for example, is accounted for by treating the adjective as an event predicate which modifies an event that is specified as the head noun’s function as part of its compositional lexical representation.

Another significant strand of polysemy research proceeds within **Cognitive Linguistic** approaches. The general aim is to study the kinds of conceptual processes that motivate the multiple meanings of linguistic forms and how these meanings may be grounded in human experience. As it is argued that lexical categories exhibit the same kind of prototype structure as other conceptual categories, the relations of polysemous senses are usually modeled in terms of radial, family resemblance categories. In these polysemy networks, the senses are typically either directly or indirectly related to a prototypical sense through such meaning extensions processes as conceptual metaphor and metonymy and image-schema transformations (Lakoff, 1987). As Cognitive Linguists also assume that all of linguistic structure, including grammar, is meaningful, some work within this approach has extended the applicability of the notions of polysemy and homonymy beyond lexical semantics to grammatical categories and constructions (Goldberg, 1995). While most other approaches dismiss homonymy as accidental and uninteresting, the relevance of diachronic processes to meaning representation in Cognitive Linguistics means that making hard and fast distinctions between homonymy, polysemy, and vagueness is not necessary (Tuggy, 1993; Geeraerts, 1993).

Polysemy and homonymy thus represent two central notions in lexical semantics, inspiring active research interest.

Possible Worlds: Philosophical Theories

D Gregory, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Anyone who reads contemporary philosophy will soon encounter talk of possible worlds, and anybody who delves a little deeper will quickly discover that there are various conflicting philosophical accounts of their nature. We consider those competing accounts, but it is helpful to begin with a discussion of the ends that possible worlds are commonly made to serve.

Possible worlds made their debut on the current philosophical scene through Kripke's work on the metamathematics of modal logics, but their current ubiquity probably owes more to their relationships to less esoteric matters. We commonly express claims about what is possible by using statements that appear to assert the existence of 'possibilities,' for example, or of 'ways things might have been.' So, for instance, somebody might assert, quite unexceptionably, that 'there's a possibility that the world will end in the next 10 years.'

That habit has striking affinities with one of the characteristic principles concerning worlds, that what is possible at a given world w is what obtains at some world that is possible relative to w . Another central principle invoking worlds relates to necessity: what is necessary at a given world w is what holds at every world that is possible relative to w . That last principle in fact follows immediately from the previous one (and vice versa) on the assumption that worlds are *complete*, in the sense that each proposition is either true at a given world or false at it.

The above theses may be interpreted in numerous ways, depending upon how their talk of 'possibility,' 'necessity,' and 'possible worlds' is read. For instance, the first principle can be construed as concerning the *physical* possibilities at a given world – whatever is compatible with the fundamental physical nature of that world – so long as we restrict the 'worlds' there considered to those that are *physically* possible relative to the relevant possible world. And if we impose

that restriction upon the possible worlds cited in the second principle, it can be treated as applying to physical necessities.

Another central assumption involving possible worlds is that one among them is the *actual* world, at which precisely the actual truths obtain. That assumption combines with the various readings of the earlier theses relating to possibility and necessity to yield truth conditions for a wide variety of modal statements. So, for instance, it implies that it is actually physically necessary that P just in case P is physically necessary at the actual world. But the central hypothesis relating possible worlds to physical necessities implies that P is physically necessary at the actual world just in case P holds at every world that is physically possible relative to the actual world.

The various theses just considered are perhaps the least contentious principles featuring possible worlds (another, more contentious but widely accepted use for worlds is in providing truth conditions for counterfactual conditionals, like 'if tigers had 10 legs they would be cumbersome'). Elsewhere, contention is the order of the day. Thus some philosophers, like David Lewis, have claimed that possible worlds can be used to provide thoroughly nonmodal analyses of modal claims. But others, like Alvin Plantinga, have disagreed. And some philosophers – Lewis again, for instance – hope to reduce propositions to classes of worlds, whereas others prefer to follow Robert Adams and Arthur Prior in identifying possible worlds with special sorts of propositions, or with set-theoretical constructions based upon propositions.

There is disagreement, then, over what it is reasonable to expect from possible worlds – that is, over what we can sensibly hope to use them *for*. Those differences are echoed in the varying theories of what possible worlds are. For it is commonly held that the concept of a possible world is a *functional* one: possible worlds are those things that are fit to play certain roles in philosophical theorizing about modality and related matters. But if one philosopher thinks a certain range of roles should be filled by possible

worlds, while another believes that worlds should serve a somewhat different range of roles, their accounts of which things are possible worlds may consequently diverge simply because the two philosophers have focused on groups of jobs that call for different occupants.

At one end of the spectrum, Lewis attempted to make possible worlds perform an extraordinarily ambitious range of tasks (for a comprehensive outline of Lewis's views on possible worlds, see Lewis, 1986). Lewis claimed that a possible world is a group of things that are all spatiotemporally related to one another and where each thing that is spatiotemporally related to something in the group is also among its occupants. So, for instance, the actual world contains precisely those things that stand in a spatiotemporal relation to you or me.

Lewis used his nonmodal account of the nature of possible worlds to provide wholly nonmodal analyses of modal locutions. He also followed the common practice of using talk of possible worlds in formal semantical treatments of fragments of natural language. And he identified numerous types of entities that philosophers and nonphilosophers have posited, such as properties and propositions, with set-theoretical constructions founded on possible worlds and their inhabitants. Another important aspect of Lewis's position is his denial that distinct possible worlds ever share any inhabitants. This led him to develop *counterpart theory*, according to which a statement regarding a certain individual belonging to a given possible world *w* – 'Kant had a beard,' for instance – is true in another possible world *y* just in case *y* contains a bearded entity that is sufficiently similar to Kant.

Although Lewis argued with great virtuosity that his putative possible worlds would perform the various tasks that he considered and that we ought therefore to believe that his worlds exist, some of his theory's obvious consequences are so implausible that few people have been willing to accept his conclusions. For instance, there might have been talking donkeys. So, Lewis claimed, there is a group of spatiotemporally interrelated items that includes a talking donkey. Hence, a talking donkey exists even if none *actually* exists – that is, a talking donkey exists even if we do not stand in any spatiotemporal relations to such a beast.

Lewis placed great emphasis upon his theory's provision of nonmodal analyses of modal locutions and argued that none of his view's major competitors could also provide them. But some of his opponents would distance themselves from Lewis's reductionist aims. Indeed, a significant lacuna in Lewis's case for his position is that he never provided a compelling account of why we should want nonmodal analyses

of modal locutions. For unless one is already persuaded of the desirability of such analyses, one of the chief supposed virtues that Lewis claimed for his stance seems instead to be a mere curiosity.

Following van Inwagen (1986), Lewis's theory may be described as *concretist*, because his possible worlds and their inhabitants are concrete rather than abstract. Lewis's view thus contrasted with the preponderance of accounts of possible worlds, on which possible worlds are identified with paradigmatically abstract items of some kind or another. For example, Adams (1974) identified possible worlds with special sets of propositions where propositions were assumed to be a variety of abstract object; Plantinga (1974) identified possible worlds with a certain type of states of affairs, another putative type of abstract item; and Stalnaker (1976) identified worlds with a particular variety of ways things might have been, which he took to be a sort of property.

Theorists who identify possible worlds with abstract entities – *abstractionists*, to use some more of van Inwagen's terminology – need not endorse highly revisionary views concerning what concrete objects exist. That fact makes their general approach more immediately appealing than Lewis's concretism. Of course, if abstractionists are to respect our ordinary modal opinions, they must still posit very many abstract objects; each total possible state of the world should correspond to a possible world. But we appear to accept that the abstract domain is immensely populous (we seem to believe in infinite collections of numbers, for instance), and that fact may make us jib less, perhaps irrationally, at the hefty ontologies that abstractionists require as compared to equally large concretist ontologies.

Abstractionists nonetheless have some work to do if they are to make the ontological foundations of their theories credible. Russell's discovery that the guiding principles of naive set theory are inconsistent showed that one cannot be assured that there really are abstract items answering to every intuitively appealing map of a portion of the abstract realm. Abstractionists therefore need to persuade us that the abstract things with which they identify possible worlds exist. To take a specific case, why should we believe in the abstract states of affairs that Plantinga equates with possible worlds? At the least, Plantinga should present a strong case that the conception of states of affairs that underlies his approach is consistent. Similar remarks apply to the other abstractionists mentioned earlier, Adams and Stalnaker.

As stated earlier in this article, Lewis argued that abstractionist accounts of possible worlds cannot provide nonmodal analyses of modal statements. So what can abstractionists do with their putative

possible worlds? They can use them to supply truth conditions for many modal claims, for one thing, although those truth conditions may not be stated nonmodally. (On Adams's theory, for instance, the supplied truth conditions will speak of 'consistent' sets of propositions). And they can provide interpretations of those philosophical discussions, which, rather than address the question of what possible worlds are, instead take possible worlds for granted and proceed to frame modal arguments and theses by speaking of them. While those tasks may seem trifling when compared to the more spectacular reductionist uses for possible worlds proposed by Lewis, they should not be dismissed – as noted at the outset, the spread of possible worlds through recent philosophy is, after all, owed to their use in precisely those ways and not to a widespread conviction that the modal ultimately boils down to the nonmodal.

An apparently simple method, described clearly by Lewis at various points in his writings, has very often guided philosophical investigations into the nature of possible worlds: one lines up the various contending accounts; one then compares their costs and benefits; and one opts for the position that comes out best overall. But although that methodology looks straightforward, its correct application requires a prior determination of philosophical virtues and vices, and the latter task is not trivial. So, for instance, how are to decide whether Lewis's nonmodal theory of possible worlds should be preferred on that account to the modal theories frequently offered by abstractionists? And how are we to adjudicate the sometimes competing demands of commonsense modal opinion and theoretical elegance?

Those and similar questions have perhaps been a little neglected by philosophers of modality, and further investigation into their answers might breathe life into a debate that has lately looked somewhat stalled. Accounts of possible worlds proliferate, but attempts to figure out what precisely we should

demand from such theories are surprisingly scarce. This would be understandable if the discussion were to manifest a high degree of well-grounded consensus on the underlying desiderata, but that condition is evidently unsatisfied: what looks like a philosophical imperative to one philosopher – the need to avoid modal primitives of one kind or another, say, or to ensure that first-order modal logic has certain inferential features – can often appear a mere fetish to another. Of course, it may be that the current debate merely reflects the fact that we cannot realistically aim for wholly satisfying answers to the sort of questions just identified; but that prognosis is a dismaying one that we should not lightly accept.

Pragmatic Determinants of What Is Said

E Borg, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

Imagine that Jack, pointing at a book on the table, utters the sentence "That is better than Jill's book." What, we might ask, is said by his utterance? Well, since the sentence contains a context-sensitive expression – the demonstrative 'that' – we know that

determining what is said will require an appeal to the context of utterance to provide a referent. Thus, this is one kind of pragmatic determinant of what is said by Jack's utterance. The sentence is also context sensitive in another, slightly less obvious, way: it is in the present tense, so an appeal to the context of utterance will also be needed to fix a time for Jack's claim. Finally, many theorists recently have argued that the sentence is also context sensitive in a third, much less

obvious, way: for to grasp what is said by Jack it seems that we also need to know what kind of relationship he envisages between Jill and her book. Does Jack intend to say that the book he is demonstrating is better than the book Jill wrote, better than the book Jill owns, the book Jill is reading, etc? And what does he mean by 'better' here – better written, better researched, better for standing on to reach a high shelf? Surely Jack says more than merely that the book he is demonstrating is better in some respect or other than a book bearing some relationship or other to Jill, but, if so, then any such additional information can only come from consideration of the context of utterance.

Furthermore – and this is where the current case differs from that of demonstratives and tense – it's not obvious that this last type of pragmatic determinant of what is said is traceable to any overt (i.e., syntactically represented) context-sensitive element. Jack's utterance does contain the syntactically marked possessive, but 's certainly doesn't appear on the list of usual suspects for context-sensitive expressions. And in many cases even this degree of syntactic representation is missing. Consider an utterance of "It's raining," where what is said is that it is raining at some location, I, or "You won't die," saying that you won't die from that cut, or "Nietzsche is nicer," meaning that Nietzsche is nicer than Heidegger. Or again, consider the speaker who produces a nonsentential utterance, e.g., pointing at a child and saying "George's brother," thereby conveying that he is George's brother. In all these cases we have additional information contributed by the context of utterance yet which seems unmarked at the syntactic level.

These types of pragmatic determinant of what is said (i.e., contextually supplied information which is semantically relevant but syntactically unmarked) have come to be known as 'unarticulated constituents' (UCs). Such elements are extremely interesting to philosophers of language since they seem to show that there are problems with a quite standard conception of formal semantics, according to which the route to meaning runs along exclusively syntactic trails.

Now, as noted above, even in formal theories of meaning, like truth-conditional accounts (*see Truth Conditional Semantics and Meaning*), some appeal to a context of utterance must be made in order to cope with overtly context-sensitive expressions. However, the thought has been that this need not contravene the essentially formal nature of our theory, since the contextual instructions can be syntactically triggered in this case (crudely, the word 'that' tells us to find a demonstrated object from the context of utterance). Much more problematic, then, are pragmatic determinants of what is said which apparently lack any

syntactic basis, for they show that context can come to figure at the semantic level regardless of whether it is syntactically called for (thus there will be no purely syntactic route to meaning).

In response to the challenge posed by UCs, advocates of formal semantics have sought to reject the idea that there are any such things as syntactically unrepresented but semantically relevant elements, claiming either that

1. every contextual element of what is said really is syntactically represented, even though this fact may not be obvious from the surface syntax of a sentence (i.e., there is more to our syntax than initially supposed), or that
2. any contextual contributions which are not syntactically marked are not semantically relevant (i.e., there is less to our semantics than initially supposed).

The first of these moves is pursued by a number of theorists who argue that, if one pays proper attention to all the information given at the syntactic level, one will find that many cases of supposedly syntax-independent semantic contribution are, in fact, syntactically required (see Stanley, 2000; Stanley and Szabo, 2000; Taylor, 2001; Recanati, 2002). Now, that there is some discrepancy between surface form and underlying syntax is a well-rehearsed point. For instance, Russell's theory of descriptions invokes a clear distinction between surface form and logical form. Furthermore cases of so-called syntactic ellipsis (like the contraction in "Jack likes dogs and so does Jill," where the second sentence is held to have the underlying syntactic form "Jill likes dogs" despite its reduced verbal form) show that surface constituents may be poor indicators of syntactic elements. If this is correct, then the principle that there is more to our syntax than is apparent at first glance is independently well motivated.

Given this, there certainly seem to be cases in which (1) is an appealing response to putative examples of UCs. To give an example: someone might claim that, because an utterance of "Jack plays" can be used in one context to say that Jack plays the trombone and in another to say that Jack plays football, there must be a syntactically unmarked, contextual contribution to the semantic content of an utterance of this kind. However, closer inspection of the syntax shows this conclusion is dubious: 'plays' is a transitive verb requiring a subject and an object and, although the argument place for an object can be left unfilled at the surface level without this making the sentence ill formed, it might be argued that the additional argument place is marked in the underlying syntax of the verb. Since 'plays' is a transitive verb, the competent interlocutor will, on hearing "Jack plays," expect to

look to a context of utterance to discover what Jack plays, but this is precisely because she is sensitive to the syntactic structure of English in this case. Thus sometimes an appeal to an enriched syntax seems the best way to cope with putative UCs. However, there are also cases where (1) seems less compelling. For instance, in certain contexts, it seems that Jack can use an utterance of “The apple is red” to convey the proposition that the apple is red to degree n on its skin. Yet it is far from clear that the correct syntactic structure for color terms includes argument places for the shade, or precise manner of instantiation, of the color. Furthermore, the idea that syntactic structure can outstrip surface form at all (or at least in the ways required by [1]) has been rejected by some.

So, the opponent of UCs might seek to supplement (1) with (2), allowing that some contextually supplied information is not marked at the syntactic level but denying that such information is semantically relevant. The advocate of this kind of response wants to accept that, at an intuitive level, the speaker who utters “The apple is red” (or “You won’t die,” etc.) clearly does convey the contextually enriched proposition (i.e., that the apple is red on the outside, or that you won’t die from that cut) but that this is an instance of speaker meaning rather than semantic content (*see Semantics–Pragmatics Boundary*). Now, whether this move is warranted in all cases is again something of a moot point. One objection might be that it is a mistake to seek to separate speaker intuitions about what is said and claims of semantic content to the radical degree predicted by this kind of move. So, for instance, it seems that the message recovered from an utterance of “That banana is green” will always be that that banana is green in some salient respect, but if this is the kind of proposition competent speakers can and do recover in communicative exchanges, shouldn’t this be what semantics seeks to capture? What role could there be for a more minimal kind of semantic content (e.g., which treats semantic content as exhausted by the proposition that that banana is green *simpliciter*)? (See Borg, 2004; Cappelen and Lepore, 2005, for attempts to answer this question.) A second worry for the formal semanticist who pursues (2) is that it may undermine her claim that semantics deals with complete propositions or truth-evaluable items. For instance, take the situation where the book Jack demonstrates is better than the book Jill is reading, but worse than the book she wrote. To assess Jack’s opening utterance as true or false in this situation, it might seem that we need first to determine what relationship Jack intended by his utterance of “Jill’s book.” Without this pragmatically determined aspect of what is said, it is argued, the sentence Jack

produces is simply not truth evaluable, it doesn’t express a complete proposition (cf. Recanati, 2003).

Clearly, then, although the formal semanticist can respond to the challenge of UCs with moves like (1) and (2) it is not at all obvious that these responses are sufficient. However, we should also be aware that there are problems to be faced on the other side, by the proponent of UCs, as well. One major worry is how to preserve our intuitive distinction between semantically relevant elements and elements which are only pragmatically relevant. Given the traditional conception of formal semantics, the answer to this question was clear: something is semantically relevant if it can be traced to the syntax of the sentence, it is pragmatically relevant otherwise. Once we admit of semantically relevant but syntactically unmarked elements, however, this way of characterizing the distinction is clearly unavailable, so the proponent of UCs owes us some other account. If Jack utters “I’ve eaten” then it might seem plausible to claim that the semantic content of this utterance is that he has eaten breakfast today, but he might also succeed in conveying the messages that he has eaten a cooked breakfast within the last hour, or that he is not hungry, or any number of further propositions. How do we decide which elements come to figure in the supposed semantic content of the utterance, and on what basis do we rule some conveyed messages as merely pragmatic?

A further worry seems to be that, for each additional contextual contribution we introduce, this contribution is itself open to further qualification: an utterance of “That banana is green” might intuitively be contextually enriched to that banana is green on its skin, but why stop here? Does the speaker mean to say that that banana is green all over its skin, that that banana is mostly green on a particular patch of skin, or that that banana is a bit green on this bit of surface skin and to a depth of degree n through the skin? The problem is that, for any piece of contextual information we introduce via a UC, this piece of information is itself likely to allow for a number of different contextual qualifications or sharpenings, and we seem to lack any principled reason to disallow these further sharpenings from appearing as part of the semantic content of the utterance. Yet, without such a reason, we run the risk of being launched on a slippery slope whereby the meaning of every utterance turns out to be a proposition which is somehow ‘complete’ in every respect. Yet no such conclusion seems palatable: it undermines notions of systematicity for meaning and makes it completely unclear how we ever come to learn and use a language given our finite cognitive resources (*see Compositionality: Semantic Aspects; Compositionality: Philosophical Aspects; Systematicity*).

So, it seems there are problems on both sides of the debate here and the question of how to handle pragmatic determinants of what is said remains a vexed one. The advocate of formal semantics needs to deliver an account both of overtly context-sensitive expressions – the indexicals, demonstratives, and tense markers of a natural language – and of the more covert kinds of context sensitivity discussed here. Reflecting on the multitude of ways in which a context of utterance can apparently affect issues of linguistic meaning certainly seems to show that the formal semanticist runs the risk of undervaluing the role played by pragmatic determinants in what is said. Yet it remains to be seen whether this constitutes merely a potential oversight on her behalf (cf. Stanley, 2000; Stanley and Szabo, 2000; Borg, 2004) or a fundamental failing of the whole approach (cf. Sperber and Wilson, 1986; Carston, 2002).

Predication

S Rothstein, Bar-Ilan University, Ramat Gan, Israel

© 2006 Elsevier Ltd. All rights reserved.

The predication relation was introduced into discourse about language by Aristotle in 'On Interpretation,' (paragraphs 5 and 6) when he defined a proposition as an instance of predication, which "asserts or denies something of something." He thus introduced into philosophical and linguistic discussion two central ideas: (a) the syntactic idea that a proposition has a binary structure, with one element, the subject, making reference to an entity and the other expressing a property, and (b) the semantic idea that asserting a proposition involves an act of asserting that an object, the reference of the subject argument, has a property expressed by the predicate. Thus, an assertion of *John is happy* is true if the denotation of the subject argument *John* has the property expressed by the predicate *is happy*.

The concept of predication played a central role in traditional grammatical discourse, and the division of a sentence into subject and predicate, became a commonplace of traditional parsing techniques. However, an understanding of what a subject and predicate actually might be waited until the techniques of modern logic and linguistics, when two questions in particular came to the center of the discussion. The first is the question of why the predication relation is so important, which could be discussed only after Frege had formulated his distinction between saturated and unsaturated linguistic entities. The second question is why one referential argument, the subject, has a privileged or distinguished position in the sentence, and progress on this point had to wait for the structural tools of modern generative syntax. This issue in fact never arose for Aristotle, since he dealt only with single-argument sentences such as *The ship sailed*, but it arises as soon as we look at sentences such as *The sailors sailed the ship*.

The major breakthrough for predication (and in fact semantics in general) came with the work of Frege at the end of the 19th century. Frege drew the distinction between saturated and unsaturated expressions. A formally unsaturated expression is an expression that contains an empty position filled by a variable, as in the mathematical expression $x + 2$, whereas a saturated expression is one that we naturally think of as denoting an object (for Frege, either an individual or a truth value). An unsaturated expression, or function, applies to a saturated expression or argument and yields a value or an output. Thus $x + 2$ applies to an argument, for example 3, to yield a value that is the denotation of the saturated expression. In this case, the value of the saturated expression $3 + 2$ is the same as the denotation of 5.

Frege saw that linguistic expressions could be analyzed in the same way. The expression *The capital city of x* can be analyzed as a function that has as its denotation, or value, a different city depending on which name replaces the variable x . *The capital city of Germany* denotes Berlin and *The capital city of the UK* denotes London. Similarly, a predicate such as *x is happy* can be applied to an argument expression such as *John* or *the boy* to yield a sentence, which has the value true or false, depending on whether or not John is or is not happy.

Frege's insight that complex expressions could be built up compositionally from simple saturated and unsaturated expressions, by a recursive process of functional application, was at the root of much progress in logic and semantics, as can be seen in the work of Montague (1970) and the formal semanticists who followed, and the work of Bar-Hillel and the categorical grammarians, all of whom focused on issues of compositionality. The issue of predication entered the syntactic discourse through the seminal work of Halliday (1967), who drew attention to secondary predicates, which were predicated of and expressed properties of local subjects, rather than sentential subjects. Halliday (1967) brought to the attention of linguists that predicative adjectives occurred with quite a limited range of meanings in constructions such as (1), and that the relation between the predicate and its local subject (in bold and italics, respectively) mirrored the semantic relation between the predicate of a sentence and the sentential subject, in the sense that if the sentence asserted was true, the subject had to have the property expressed by the predicate.

- (1a) Mary painted the *house* **red**.
- (1b) *John* drove the car **drunk**.
- (1c) John drove *the car* **broken**.

Example (1a) is an instance of resultative predication, with the AP predicate expressing a property that the subject is asserted to have at the end of the action

expressed by the verbal predicate; (1b) and (1c) are examples of depictive predication, with the AP predicate expressing a property that the subject is asserted to have while the action expressed by the verbal predicate is going on. Resultatives are typically predicated of direct object arguments, while depictives, as the examples in (1) show, may be predicated of subject or direct object arguments.

It was Edwin Williams, who in a series of papers (Williams, 1980, 1983, 1987) brought predication into the domain of generative syntax. Although there had been quite a lot of discussion around the notion of subject, Williams was the first to tie it into a discussion of the subject predicate relation. For him, the central questions were how to explain the syntactic relation of a secondary predicate to its subject (in more modern theoretical language, to explain how the predicate AP is licensed, or integrated into the structure of the sentence), how to explain why the subject argument is distinguished, and how to draw the appropriate structural parallels between secondary and main clause predicates. He argued that predication is essentially a thematic relation, and that the syntactic predication relation was expressed via the assignment of thematic roles. A lexical head assigns thematic roles to its thematic arguments, and in general all but one of the thematic arguments is assigned to an argument syntactically realized inside the projection of the thematic head. The thematic role assigned outside the projection of the head is external. Williams argued that the subject of a predicate is the argument assigned an external argument, and the primacy of the subject follows from the basic syntactic distinction between external and internal arguments. Thus, in a sentence such as (1a), assigned the structure in (2), the adjective *red* assigns a thematic role outside the maximal AP projection that it heads to *the house* and that therefore is its subject. Williams showed that this mechanism of external theta-role assignment could be used to express sentential subject predicate relations also. In (1a), *Mary* is assigned a thematic role 'agent' by *paint* outside the VP projection of the head, and is thus the subject of the whole predicate *paint the house red*.

What Williams captured precisely in this account is the duality of the relation between the sentential subject and the verb: the subject is a thematic argument

of the verb, but subject of the whole predicate phrase that the verb heads. Williams was not explicit about the semantic interpretation of the predication relation, but he assumes that the adicity of the lexical head (the number of thematic roles it assigns) directly reflects the adicity of a semantic relation denoted by the lexical head and that thematic role assignment is a syntactic reflection of a semantic relation. Williams was thus making implicit use of Frege's classification of linguistic objects into saturated and unsaturated. This became explicit in Williams (1987), where he presents an account of the mapping between syntactic representation and semantic representation, where he argues that unassigned thematic roles are interpreted as unsaturated variables in the semantic representation. Furthermore, argument traces (NP, or rather DP, traces) are to be analyzed as variables in the same way, and thus NP movement is ultimately reducible to the predication relation.

Rothstein (1983) and later Rothstein (1995, 2001) followed Williams in identifying predication as a central mechanism in syntactic theory, but argued against identifying syntactic unsaturatedness with unassigned thematic roles. She argued that in order to analyze a sentence generally as an instance of a predication relation, it is necessary to recognize cases of predication that do not involve a thematic relation between the head of the predicate and the subject. This is because of the existence of pleonastics, or non-thematic subjects, examples of which are given in (3):

- (3a) It seems that John will not arrive on time.
- (3b) Il a été mangé trois pommes. (French)
it has been eaten three apples.
'Three apples have been eaten.'
- (3c) ze meatzben Se dani meaxer. (Hebrew)
it irritates that dani is late.
'It is irritating that Dani is late.'

Rothstein argued that the Fregean saturated/unsaturated distinction is a primitive typal syntactic distinction between two different kinds of syntactic constituents: arguments and predicates. The typically referential constituents, DP and CP, are syntactically saturated and canonically serve as arguments, while the AP, PP, VP, and NP constituents are inherently unsaturated and can serve as predicates. Unsaturated constituents are typically saturated either directly or indirectly by predication (although NP arguments are saturated via determiner binding when they appear in argument position). Crucially, the syntactic relation between the pleonastic subject *it* in (3a) and the VP *seems that John will not arrive on time* is exactly the same predication relation as holds between the subject *John* and predicate *is happy* in the sentence *John is happy*. Rothstein argued that under this analysis,

the distribution of pleonastic subjects in English could be completely predicted, and that the obligatoriness of the subject (expressed in Chomsky's 1982 Extended Projection Principle) could be explained. In particular, she gave an account of the obligatoriness of the pleonastic in complement position of verbs such as *consider*, illustrated in (4a), in which she argues that pleonastics appear as the subject of small clause predications, and of the optional movement of CP direct objects to subject position illustrated in (4b):

- (4a) I consider it ridiculous that John is late again.
- (4b) It has long been believed that the earth is flat.

In this approach, thematic subjects are just a proper subset of subjects, and thematic role assignment to subject position uses the predication relation, just as thematic role assignment to internal arguments is via Case assignment relations or prepositions. Rothstein argued that there were two different kinds of predication: primary, or clausal, predication and secondary, or adjunct, predication. The particular constraints on adjunct predication (see Rothstein, 2003) mean that secondary predicates are essentially thematic, while primary predication need not be so.

Another approach to predication, which starts from different assumptions, but has some of the same syntactic consequences as Rothstein's, is Gennaro Chierchia's. Working within the framework of property theory, he proposed treating semantic properties as having two modes of presentation, an unsaturated predicate and its individual property correlate, π . He is concerned primarily with semantic issues, in particular, how properties can be predicated of themselves, as in *Being wise is wise* or *Cheerfulness is cheerful*. In Chierchia's theory, a VP denotes a saturated property, and Inflection denotes a function from individual properties into propositional functions, which applies to a VP and yields a propositional function, independently of whether the VP requires a thematic subject. Chierchia differs from Rothstein, who claims that the VP is formally a predicate, and he does not extend his theory to deal with noninflected predicates, but both approaches have in common that the clause is structurally constrained to be an instance of predication, independent of the thematic properties of the predicate or its head. Positing a structural, nonthematic predication relation has been quite fruitful in terms of syntactic explanatoriness. The structural approach to predication has been quite productive in leading to analyses of propositional structure, in particular with respect to the distribution of pleonastics and nonthematic predicates and copula constructions.

A second direction on which predication studies have focused has been the variety and differing

properties of secondary predicates crosslinguistically. As mentioned above, there seem to be two kinds of secondary predicates, resultatives and depictives, where resultatives are generally restricted to taking direct objects as their subjects, while depictives can apply to both subjects and objects. Much work has focused on the particular syntactic properties associated with different secondary predicates in different languages, for example with the structural constraints on subject predicate relations (Demonte, 1986), Case properties associated with different secondary predicates (especially in Russian, e.g., Filip, 2001), whether secondary predicates are independent predicates or form a lexical complex predicate with the verb in Germanic (Neeleman, 1994; Neelman and Weerman, 1993; Wunderlich, 1997), whether or not resultatives are truly oriented toward the direct object, (Rappaport Hovav and Levin, 2001; Wechsler, 1997; Kim, 1993), and how best to capture the semantic constraints on their interpretations. Some of the most interesting syntactic work in recent years has emerged from the attempts to give a unified semantics for depictive and resultative secondary predicates (see, e.g., Rothstein, 2003) and work by Cormack and Smith (1994, 1999), who suggest that secondary predication should be seen as a kind of serial verb construction for languages that do not otherwise allow them. While this idea has not yet been worked out in any detail, it seems a potentially fruitful direction in which to take the syntax of predication.

Presupposition

Introduction

A presupposition is a semantic property of a sentence making that sentence fit for use in certain contexts and unfit for use in others. This property is partly based on the fact that if a sentence *B* presupposes a sentence *A* ($B \gg A$), then *B* entails *A* ($B \models A$): whenever *B* is true, *A* is necessarily also true, given the same situation referred to, in virtue of the meanings of *B* and *A*. Presuppositions (*P-entailments*) are thus a subclass of entailments. Entailments that are not presuppositional are *classical* or *C-entailments*. (1) illustrates a C-entailment (\models_c); (2a–d) illustrate P-entailments (\gg):

- (1) Jack has been murdered. \models_c Jack is dead.
- (2a) Jack lives in Manchester. \gg Jack exists.
- (2b) Jill has forgotten that Jack is her student. \gg Jack is Jill's student.
- (2c) Jack is divorced. \gg Jack was once married.
- (2d) Only Jack left. \gg Jack left.

(2a) illustrates *existential presupposition*. (2b) exemplifies *factive presuppositions* (Kiparsky and Kiparsky, 1971): the factive predicate (*have forgotten*) requires the truth of the *that*-clause. (2c) is a case of *categorical presupposition*, derived from the lexical meaning of the main predicate (*be divorced*). (2d) belongs to a *remainder category*, the presupposition in question being due to the particle *only*.

There are various differences between P-entailments and C-entailments. When $B \gg A$, *A* is somehow 'prior' to *B*, restricting the domain within which *B* is interpretable. Presuppositions present themselves specifically, whereas C-entailments are 'unguided' and thus lack the function of restricting the interpretation domain. This makes presupposition relevant for the cognitive aspects of linguistic information transfer.

There is also a logical difference, especially regarding *negation*, the central operator in any logic.

In standard logic a sentence that is false for any reason whatsoever is made true by the preposed negation. In language, however, negation is sensitive, in default uses, only to C-entailments, leaving the P-entailments intact. Suppose (2d) is false on account of a C-entailment's falsity, for example because other people left as well. Then (3a), the negation of (2d), is true and (3b) is coherent, as expected. Not so when a P-entailment of (2d) is false, as in (3c), where the presupposition 'Jack left' is denied. (3c) is incoherent because *Not only Jack left* still presupposes that Jack left ('!!' indicates incoherence):

- (3a) Not only Jack left.
- (3b) Not only Jack left: other people left as well.
- (3c) !!Not only Jack left: Jack did not leave.

This raises the question of the truth value of (3a) in cases where, say, Jack did not leave. In standard logic, the entailment from both (2d) and its negation (3a) to *Jack left* means that if Jack did not leave, both (3a) and (2d) are false simultaneously, which violates the Principle of Contradiction ('a sentence and its negation cannot be true or false simultaneously'). Standard logic thus rules out falsity for *Jack left*, because its falsity leads to a contradiction. This makes *Jack left* a necessary truth. But *Jack left* is, if true, contingently so. Therefore, standard logic is inadequate for presuppositions.

Many feel that this calls for a rejection of the Principle of the Excluded Third or PET ('any sentence expressing a proposition is either true or false, without any values in between or outside') and for the introduction of a *third truth value* into the logic of language. Others prefer to keep standard bivalent logic intact and seek a *pragmatic* way out in terms of conditions of use. This question is discussed in the next section.

Operational Criteria

Presuppositions are detectable ('observable') irrespective of actual token use. Like C-entailments, P-entailments can be read off isolated sentences,

regardless of special context. Yet they evoke a context. (2a) requires it to be contextually given that there exists someone called 'Jack' and thus evokes such a context, asserting that he lives in Manchester; (2b) evokes a context where Jack is Jill's student, asserting that Jill has forgotten that; (2c) requires a context where Jack was once married, and asserts that the marriage has been dissolved; and (2d) requires a context where Jack left, while asserting that no one else left. This, together with the entailment criterion, provides a set of operational criteria to recognize presuppositions.

First, if $B \gg A$ then $B \models A$. The usual heuristic criterion for an entailment $B \models A$ is the incoherence of the juxtaposition of *not*(A) with B. On the whole, this suffices as a criterion. For example, (4a) does not entail, and therefore does not presuppose, (4b), because (4c) is still coherent.

- (4a) Lady Fortune neighs.
- (4b) Lady Fortune is a horse.
- (4c) Lady Fortune is not a horse, yet she neighs.

But this criterion overkills when the entailing sentence is qualified by an epistemic possibility operator, like English *may*, as in (5a), which does not entail (5b), even though (5c) is incoherent. Epistemic possibility requires compatibility of what is said to be possible with what is given in discourse or knowledge. Therefore, if $B \models A$, then with *not*(A) in the knowledge base, *possibly*(B) results in inconsistency, although *possibly*(B) does not entail A. The entailment criterion can be refined, without loss of generality, by testing the (in)coherence of the juxtaposition of *possibly* (*not*(A)) with B, as in (5d). Because (5d) is coherent, (5a) \models (5b):

- (5a) Jack may have been murdered.
- (5b) Jack is dead.
- (5c) !! Jack is not dead, yet he may have been murdered.
- (5d) Jack may not be dead, yet he may have been murdered (and thus be dead).

To distinguish P-entailments from C-entailments further criteria are needed. First there is the *projection criterion*: if $B \gg A$ and B stands under an entailment-canceling operator like *possibly* or *not* or *believe*, A survives not as a P-entailment but as a more or less strongly invited presuppositional inference ($>$). Generally, $O(B_A) > A$, where ' B_A ' stands for ' B presupposing A' and 'O' for an entailment-canceling operator. In standard terminology, the presupposition A is *projected* through the operator O. The conditions under which presuppositions of embedded clauses are projected through higher operators constitute the *projection problem of presupposition*.

Projection is typical of P-entailments, as in (6), not of C-entailments, as in (7):

- (6) Jill believes that Jack is divorced $>$ Jack was once married.
- (7) Jill believes that Jack has been murdered \nrightarrow Jack is dead.

The projection criterion is mostly used with negation as the entailment-canceling operator. Strawson (1950, 1952) held, incorrectly, that presupposition is always preserved as entailment under negation. In his view, a sentence like:

- (8) The present king of France is not wise.

still presupposes, and thus entails, that there exists a king of France, who therefore, if (8) is true, must lack wisdom. Although presupposition is, in fact, normally weakened to invited inference under negation, Strawson's 'negation test' became the standard test for presupposition. Provided the condition of 'entailment' is replaced by that of 'at least invited inference,' the test is sound.

Then there is the *discourse criterion*: a discourse bit A *and/but* B_A (with allowance for anaphoric processes) is felt to be orderly and well planned – that is, *sequential*. The condition of sequentiality is used to characterize stretches of acceptable text that have their presuppositions spelled out (' \checkmark ' signals sequentiality):

- (9a) \checkmark There exists someone called 'Jack,' and he lives in Manchester.
- (9b) \checkmark Jack is Jill's student, but she has forgotten that he is.
- (9c) \checkmark Jack was married, but he is divorced.
- (9d) \checkmark Jack left, and he is the only one who did.

C-entailments and inductive inferences behave differently. When they precede their carrier sentence the result may still be acceptable, yet there is a qualitative difference, as shown in (10a,b), where a colon after the first conjunct is more natural ('#' signals nonsequential but coherent discourse):

- (10a) #Jack is dead: he has been murdered.
- (10b) #Jack earns money: he has a job now.

The discourse criterion still applies through projection: A *and/but* O(B_A) is again sequential (the entailment-canceling operators are printed in italics):

- (11a) \checkmark Jack really exists, and Jill *believes* that he lives in Manchester.
- (11b) \checkmark Jack is Jill's student, but she has *probably* forgotten that he is.
- (11c) \checkmark Jack was once married, and he is *not* divorced.
- (11d) \checkmark Jack left, and he is *not* the only one who did.

These tests reliably set off P-entailments from C-entailments.

The Logical Problem

The Threat to Bivalence

The first to see the threat posed by presuppositions to standard logic was Aristotle's contemporary Eubulides of Miletus (Kneale and Kneale, 1962: 113–117). He formulated (besides other paradoxes such as the Liar) the paradox of the *Horned Man* (Kneale and Kneale, 1962: 114): “What you have not lost you still have. But you have not lost your horns. So you still have horns.” This paradox rests on presupposition. Read *B* for *You have lost your horns* and *A* for *You had horns*. Now $B \gg A$ (the predicate *have lost* induces the presupposition that what has been lost was once possessed).

Eubulides implicitly assumed that P-entailments are preserved under negation: $B \models A$ and $\text{not}(B) \models A$. Under PET, this would make *A* a logically necessary truth, which is absurd for a contingent sentence like *You had horns*. To avoid this, PET would have to be dropped, very much against Aristotle's wish. Although Aristotle himself was unable to show Eubulides wrong, there is a flaw in the paradox. It lies in the incorrectly assumed entailment in the first premise “What you have not lost you still have.” For it is possible that a person has not lost something precisely because he never had it.

The same problem was raised by Strawson (1950, 1952), but with regard to existential presuppositions. Like Eubulides, Strawson assumed full entailment of presupposition under negation and concluded that PET had to go. For him, nonfulfillment of a presupposition leads to both the carrier sentence and its negation lacking a truth value altogether. Frege (1892) had come to the same conclusion, though from a different angle. In a sentence like:

(12) The unicorn ran.

analyzed as ‘Run(the unicorn)’, the subject term lacks a referent in the actual world, though the existence of such a referent is presupposed. That makes it impossible to test the truth of (12): since there is no unicorn, there is no way to check whether it actually ran. Therefore, Frege (and Strawson) concluded, (12) lacks a truth value.

This posed a profound problem for standard logic in that the applicability of standard logic to English would have to be made dependent on contingent conditions of existence – a restriction no logician will accept. In the effort to solve this problem two traditions developed, the *Russell tradition* and the *Frege–Strawson tradition*.

The Russell Tradition

In his famous 1905 article, Russell proposed a new analysis for sentences with definite terms, like (13a).

Putting the new theory of quantification to use, he analyzed (13a) as (13b), or ‘there is an individual *x* such that *x* is now king of France and *x* is bald, and for all individuals *y*, if *y* is now king of France, *y* is identical with *x*’:

- (13a) The present king of France is bald.
(13b) $\exists x [\text{KoF}(x) \wedge \text{Bald}(x) \wedge \forall y [\text{KoF}(y) \rightarrow x = y]]$

In order to save bivalence, Russell thus replaced the time-honored subject-predicate analysis with an analysis in which the definite description *the present king of France* no longer forms a constituent of the logically analyzed sentence, but is dissolved into quantifiers and propositional functions.

The negation of (13a) should be (13b) preceded by the negation operator, i.e. (14a). However, Russell held, speakers often prefer, for reasons best known to themselves, to interpret *The present king of France is not bald* as (14b), with internal negation over ‘Bald(*x*)’:

- (14a) $\neg \exists x [\text{KoF}(x) \wedge \text{Bald}(x) \wedge \forall y [\text{KoF}(y) \rightarrow x = y]]$
(14b) $\exists x [\text{KoF}(x) \wedge \neg \text{Bald}(x) \wedge \forall y [\text{KoF}(y) \rightarrow x = y]]$

This makes sentences like (8) ambiguous.

This analysis, known as Russell's *Theory of Descriptions*, was quickly accepted by logicians and philosophers of language, as it saved PET. At the same time, however, it drove logicians and linguists apart, as it defies any notion of sentence structure. Moreover, the ‘uniqueness clause’ in (13b), $\forall y [\text{KoF}(y) \rightarrow x = y]$, saying that only one king of France exists, is meant to account for the uniqueness expressed by the definite article. In fact, however, the definite article implies no claim to uniqueness of existence, only to discourse-bound uniqueness of reference. Then, this analysis is limited to definite descriptions and is unable to account for other kinds of presupposition. Factive and categorial presuppositions, and those derived from words like *all*, *still*, or *only*, fall outside its coverage.

An important objection is also that negation can only cancel presuppositions when it is a separate word (not a bound morpheme) and in construction with a finite verb. In all other cases, the negation fully preserves P-entailments. Thus, (3a), with *not* in construction with *only*, preserves the presupposition induced by *only*. Moreover, sentence-initial factive *that*-clauses preserve presuppositions even though the negation is constructed with the finite verb:

- (15a) That Jack left surprised Jill \gg Jack left.
(15b) That Jack left did not surprise Jill \gg Jack left.

Likewise for cleft and pseudocleft sentences:

- (16a) It was Jack who left / The one who left was Jack \gg Someone left.
(16b) It wasn't Jack who left / The one who left wasn't Jack \gg Someone left.

When cases like these, overlooked by the authors discussed, are taken into account and the logic is kept bivalent, the presuppositions of sentences like (2d) and (3a), (15a,b), or (16a,b) would again have to be necessary truths.

The same goes for:

(17a) All men are mortal \gg There exist men.

(17b) Not all men are mortal \gg There exist men.

In standard Predicate Calculus, however, (17a) does not entail (and thus cannot presuppose) that there exist men, whereas (17b) does, because ‘not all F is G’ is considered equivalent with ‘some F is not G,’ which entails the existence of at least one F. Yet both (17a) and (17b) satisfy the operational criteria given earlier. Standard Predicate Calculus thus seems to fit the presuppositional facts badly.

To account for other than existential presuppositions some have proposed to change Russell’s analysis into:

(18) $\exists x [KoF(x)] \wedge Bald(he)$

or ‘there is a king of France, and he is bald’. *He* is now no longer a bound variable but an anaphoric pronoun. With a logical mechanism for such anaphora (as in Kamp, 1981; Groenendijk and Stokhof, 1991), this analysis can be generalized to all categories of presupposition. A sentence B_A is now analyzed as A and B_A , and $Not(B_A)$, though normally analyzed as A and $Not(B_A)$ with small scope *not*, can also, forced by discourse conditions, be analyzed as $Not(A$ and $B_A)$, with large scope *not*. This analysis, which saves PET, is known as the *Conjunction Analysis* for presupposition.

Anaphora is needed anyway, because Russell’s analysis fails for cases like (19), where quantifier binding is impossible for *it*, which is in the scope of *I hope*, whereas *I hope* is outside the scope of *I know*:

(19) I know that there is a dog and I hope that it is white.

The Conjunction Analysis, however, still cannot account for the fact that (20a) is coherent but (20b) is not:

(20a) There is a dog and it is white, and there is a dog and it is not white.

(20b) !!There is a dog and it is white and it is not white.

(20a) speaks of two dogs, due to the repetition of *there is a dog*, but (20b) speaks of only one. Yet the Conjunction Analysis cannot make that difference, because the repetition of *there is a dog* makes no logical or semantic difference for it. Attempts have been made to incorporate this difference into the logic

(e.g., Kamp, 1981; Heim, 1982; Groenendijk and Stokhof, 1991) by attaching a memory store to the model theory that keeps track of the elements that have so far been introduced existentially.

Even then, however, the Conjunction Analysis still postulates existence for term referents whose existence is denied:

(21) Santa Claus does not exist.

The Frege-Strawson Tradition

Strawson (1950, 1952) was the first to oppose the Russell tradition. He reinstated the traditional subject-predicate analysis and discussed only existential presuppositions. Negation is considered presupposition-preserving. Sentences with presupposition failure are considered truth-valueless. Strawson’s definition of presupposition is strictly logical: $B \gg A =_{Def} B \models A$ and $Not(B) \models A$. This analysis requires a *gapped bivalent propositional calculus* (GBPC), shown in Figure 1.

Insofar as truth values are assigned, GBPC preserves standard logic. Moreover, * is ‘infectious’: when fed into a truth function it yields *. Remarkably, GBPC limits the applicability of logic to situations where the presuppositions of the sentences involved are true. The applicability of GBPC thus varies with contingent circumstances.

Wilson (1975) and Boër and Lycan (1976) side with Russell and criticize Strawson, showing examples of presupposition-canceling under negation: (22a–c) are coherent, though they require emphatic, discourse-correcting accent on *not*:

(22a) The present king of France is NOT bald: there is no king of France!

(22b) Jill has NOT forgotten that Jack is her student: Jack isn’t her student!

(22c) Jack is NOT divorced: he never married!

For these authors, classical bivalent logic is adequate for language; P-entailments differ from C-entailments only pragmatically. There would be a point if (a) a pragmatic explanation were available, and (b) presuppositions were always canceled under negation. But neither condition is fulfilled.

		\wedge B			\vee B		
\sim A	A	T	F	*	T	F	*
F	T	T	F	*	T	T	*
T	F	F	F	*	T	F	*
*	*	*	*	*	*	*	*

Figure 1 Strawson’s gapped bivalent propositional calculus (GBPC). Key: \sim , presupposition-preserving negation; T, truth; F, falsity; *, unvalued.

In fact, the presupposition-canceling ‘echo’ negation NOT of (22a–c) is impossible for cases that preserve P-entailments under negation:

- (23a) !!NOT only Jack left: he didn’t leave!
 (23b) !!NOT all students protested: there weren’t any students!
 (23c) !!That Jack left did NOT surprise Jill: he didn’t leave!
 (23d) !! The one who left was NOT Jack: nobody left!

Likewise for the negation required with *negative polarity items* (NPIs) in assertive main clauses (NPIs are printed in italics):

- (24a) !!Jack does NOT *mind* that he is in trouble: he isn’t in trouble!
 (24b) !!Jack has NOT come back *yet*: he never went away!
 (24c) !!Jill has NOT seen Jack *in weeks*: she doesn’t exist!

This analysis is thus fatally flawed.

The Trivalent Solution

One may envisage a three-valued logic, identical to standard bivalent logic but for a distinction between two kinds of falsity, each turned into truth by a separate negation operator. Minimal falsity (F1) results when all P-entailments are true but not all C-entailments, radical falsity (F2) when one or more P-entailments are false. Correspondingly, *minimal negation* (\sim) turns F1 into truth (T) and T into F1, leaving F2 unaffected, whereas *radical negation* (\simeq) turns F2 into T and both T and F1 into F1.

In Kleene’s (1938) *trivalent propositional calculus*, \wedge yields T only if both conjuncts are T, F1 when either conjunct is F1, and F2 otherwise. Analogously, \vee yields T when either conjunct is T, F1 only if both conjuncts are F1, and F2 otherwise. The corresponding tables are given in Figure 2 (where the value F2 is named ‘indefinite’ or I). This logic preserves all theorems of standard logic when bivalent \neg replaces trivalent \sim . Kleene’s calculus lacks the radical negation (\simeq), but comes to no harm if it is added.

Kleene’s calculus is used by some presuppositional logicians (e.g., Blau, 1978). It is empirically problematic in that it yields F1 for ‘ $A \wedge B$ ’ when either A or B is F2 whereas the other is F1, thus allowing presupposition failure in one conjunct while still considering

the conjunction as a whole free from presupposition failure. This makes no sense in view of *and* as a discourse incrementer. Kleene’s calculus is more suitable for vagueness phenomena with F2 as an umbrella value for all intermediate values between T and F (Seuren *et al.*, 2001).

In Seuren’s presuppositional propositional calculus TPC2 (Seuren, 1985, 2001: 333–383; Seuren *et al.*, 2001) the operators \wedge and \vee select, respectively, the highest and lowest of the component values ($F2 > F1 > T$), as shown in Figure 3. Classical negation (\neg), added for good measure, is the union of \sim and \simeq , but is taken not to occur in natural language, which has only \sim and \simeq . In TPC2, F2 for either conjunct yields F2 for ‘ $A \wedge B$ ’, as required.

TPC2 is likewise equivalent with standard bivalent logic under the operators \neg , \wedge , and \vee (Weijters, 1985). Thus, closed under (\neg , \wedge , \vee) standard bivalent logic is independent of the number of truth values employed, though any value ‘false’ beyond F1 will be vacuous. Moreover, in both generalizations with n truth values ($n \geq 2$), there is, for any value $i \geq 2$, a *specific negation* N^i turning i into T, values lower than i into F1, and leaving higher values unaffected. Thus, in TPC2, N^{F1} is \sim and N^{F2} is \simeq . Classical bivalent \neg is the union of all specific negations. Consequently, in the standard system, \neg is both the one specific negation allowed for and the union of all specific negations admitted. Standard logic is thus the most economical variety possible of a generalized calculus of either type.

The Discourse Approach

Presupposition is not defined, only restricted, by its logical properties:

- (25) If $B \gg A$, then $B \models A$ and $\sim B \models A$, and
 $\sim A / \simeq A \models \simeq B$.

(25) thus specifies necessary, but not sufficient, conditions for presupposition. Were one to adopt a purely logical definition, various paradoxical consequences would follow. For example, any arbitrary sentence would presuppose any necessary truth, which would make the notion of presupposition empirically vacuous.

			$\wedge B$			$\vee B$		
$\neg A$	$\sim A$	A	T	F1	F2	T	F1	F2
F1	F1	T	T	F1	F2	T	T	T
T	T	F1	F1	F1	F1	T	F1	F2
T	F2	F2	F2	F1	F2	T	F2	F2

Figure 2 Trivalent propositional calculus (TPC1).

				$\wedge B$			$\vee B$		
$\neg A$	$\simeq A$	$\sim A$	A	T	F1	F2	T	F1	F2
F1	F1	F1	T	T	F1	F2	T	T	T
T	F1	T	F1	F1	F1	F2	T	F1	F1
T	T	F2	F2	F2	F2	F2	T	F1	F2

Figure 3 Trivalent propositional calculus (TPC2).

Attempts have been made (Gazdar, 1979; Heim, 1982; Seuren, 1985, 2000) at viewing a presupposition A of a sentence B_A as restricting the interpretable use of B to contexts that admit of, or already contain, the information carried by A . Such an approach creates room for an account of the discourse-correcting 'echo' function of presupposition-canceling (radical) NOT. Horn (1985, 1989) correctly calls NOT *metalinguistic*, in that it says something about the *sentence* in its scope – though his generalization to other metalinguistic uses of negation is less certain. Neither TPC2 nor TPC1 can account for this metalinguistic property. This means that the argument of NOT is not a sentence but a quoted sentence. NOT('B_A') says about the sentence B_A that it cannot be sequentially incremented in a discourse refusing A .

Sequential incrementation to a discourse D restricts D to a progressively narrower section of the universe of all possible situations U , making the increment *informative*. Incrementation of A , or $i(A)$, to D restricts D to the intersection of the set of situations in which D is true and the set of situations where A is true. The set of situations in which a sentence or set of sentences X is true is the *valuation space* of X , or $/X/$. For D incremented with A we write ' $D + A$ '. $D + A$ is the conjunction of D and A , where D is the conjunction of all incremented sentences since the initial U . The *sequentiality condition* requires:

- (a) for any A , $/D/$ is larger than $/D + A/$
(informativity: remember that D is restricted by A);
- (b) if $B \gg A$ then $i(A)$ must precede $i(B)$ (not so when $B \models_c A$).

If A has not already been incremented prior to $i(BA)$ it is cognitively 'slipped in,' a process called *accommodation* or *post hoc suppletion*. A text requiring accommodation is not fully sequential, but still fully coherent.

On the assumption that D , as so far developed, is true, any subsequent sentence B must be valued T or F1, because F2 for B implies that some presupposition of B , and hence D as a whole, is not true. This assumption is made possible by the *Principle of Presumed Truth* (PPT), which says that it must be possible for any D to be true. The assumption that D is actually true blocks the processing of a new sentence that would be valued F2 in D . For example, let D contain $i(\sim A)$. Now B_A is blocked, because A is valued F1 (assuming that D is true). But NOT('B') can be incremented and is true under PPT, as it says about B that it cannot be incremented.

Therefore, $/D/$ must contain situations with sentences as objects. Cognitively speaking, this is perfectly

plausible, because speakers are aware of the fact that they utter words and sentences. That awareness enables them to refer back to words and sentences just uttered or expected to be uttered. Words and sentences as objects are a necessary corollary of any speech utterance. This corollary underlies the free mixing of object language and metalanguage in natural language. The prohibition issued by logicians against such mixing has no ground in natural language (Seuren, 2001: 125–130).

Natural language negation is, in a sense, ambiguous (depending on syntactic conditions) between presupposition-preserving (minimal) *not* and presupposition-canceling (radical) NOT. Many find this unacceptable, because ambiguities are normally language specific, whereas this ambiguity would appear to be universal. Yet the obvious question of what would be the overarching single meaning of the negation in all its uses has not, so far, been answered. Similar problems occur with other logical operators, especially with *and*, *or*, and *if*, as the following examples show:

- (26a) Do as I say and you will be a rich man.
- (26b) Don't come nearer, or you'll be a dead man.
- (26c) That's awful, or should I say 'dreadful'?
- (26d) Let's go home, or do you have a better idea?
- (26e) If you're tired, I have a spare bed.

In the case of *not* and the other logical operators, speech act factors as well as factors of metalinguistic use play an important role. Unfortunately, the grammar and semantics of both speech acts and metalinguistic use are still largely unexplored. Horn (1985) pointed out that English *not* is often used metalinguistically, as in:

- (27a) Not Lizzy, if you please, but the Queen is wearing a funny hat.
- (27b) She wasn't happy, she was ecstatic!

And he classifies radical NOT with the other metalinguistic cases. However, as pointed out in Seuren (2001: 345–347), NOT, though metalinguistic, differs from the other cases in that it can only occur in construction with the finite verb (the 'canonical position'), whereas the other metalinguistic negations can occupy any position normal *not* can occur in. (28a) is coherent, with a canonically placed NOT, but (28b,c), likewise with NOT, are incoherent, as NOT is in a non-canonical position:

- (28a) He did NOT only lose \$500. He only lost \$20.
- (28b) !!NOT only did he lose \$500. He only lost \$20.
- (28c) !!He NOT only lost \$500. He only lost \$20.

The question of the overall meaning description of the logical operators, in terms of which their strictly logical meaning would find a place, defines a research

project of considerable magnitude – a project that has so far not been undertaken in a coordinated way.

The Structural Source of Presuppositions

The source of at least three of the four types of presupposition distinguished earlier lies in the satisfaction conditions of the main predicate of the carrier sentence. The satisfaction conditions of an n -ary predicate P^n are the conditions that must be satisfied by any n -tuple of objects for P^n to yield truth. Thus, for the unary predicate *white* the conditions must specify when any object can truthfully be called 'white'. For the binary predicate *wash* they must specify when it can truthfully be said of any pair of objects $\langle i, j \rangle$ that '*i* washes *j*'.

A distinction is made between two kinds of lexical conditions, *preconditions* and *update conditions*. When a precondition is not fulfilled, the sentence is radically false; failure of an update condition yields minimal falsity. Fulfillment of all conditions gives truth.

The satisfaction conditions of a predicate P^n are specified according to the schema ($[[P^n]]$ is the extension of P^n):

- (29) $[[P^n]] = \{ \langle i^1, i^2, \dots, i^n \rangle : \dots (\text{preconditions}) \dots$
 $\quad \quad \quad | \dots (\text{update conditions}) \dots \}$
 or: 'the extension of P^n is the set of all n -tuples of objects $\langle i^1, i^2, \dots, i^n \rangle$ such that
 $\dots (\text{preconditions}) \dots$ and $\dots (\text{update conditions}) \dots$ '.

The satisfaction conditions of the predicate *bald*, for example, may be specified as follows (without claiming lexicographical adequacy):

- (30) $[[\text{Bald}]] = \{ i : i \text{ is normally covered, in}$
 $\quad \quad \quad \text{prototypical places, with hair, fur, or pile;}$
 $\quad \quad \quad \text{or } i \text{ is a tire and normally covered with tread } |$
 $\quad \quad \quad \text{the normal covering is absent} \}$

This caters for categorial presuppositions. Factive presuppositions are derived by the precondition that the factive clause must be true.

Existential presuppositions are derivable from the precondition that a specific term t of a predicate P^n refers to an object existing in the real world. P^n is then *extensional* with respect to t . *Talk about*, for example, is extensional with respect to its subject term, but not with respect to its object term, because one can talk about things that do not exist. The satisfaction conditions of *talk about* will thus be as in (31), where the asterisk on j indicates that *talk* is nonextensional with respect to its object term:

- (31) $[[\text{talk about}]] = \{ \langle i, j^* \rangle : \dots (\text{preconditions}) \dots$
 $\quad \quad \quad | \dots (\text{satisfaction conditions}) \dots \}$

The predicate *exist* lacks any preconditions and is to be specified as nonextensional with respect to its subject term:

- (32) $[[\text{exist}]] = \{ i^* \mid i \text{ is an object in the actual world} \}$

A definite subject of the verb *exist* must be represented somewhere in **D**, normally in some intensional subdomain, e.g., the subdomain of things that Jack keeps talking about, as in:

- (33) The man that Jack keeps talking about really exists.

The incremental effect of (33) is that the representation of the thing that is said to exist is moved up to the truth domain of **D**. This analysis requires the assumption of *virtual objects*.

The remainder category of presuppositions, induced by words like *only* or *still*, or by contrastive accent or (pseudo)cleft constructions, looks as if it cannot be thus derived. The choice here is either to derive them by *ad hoc* rules or to adopt a syntactic analysis in terms of which of these words and accents figure as (abstract) predicates at the level of semantic representation taken as input to the incrementation procedure.

Principles and Parameters Framework of Generative Grammar

R Freidin, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

The main task of linguistic theory “must be to develop an account of linguistic universals that, on the one hand, will not be falsified by the actual diversity of languages and, on the other, will be sufficiently rich and explicit to account for the rapidity and uniformity of language learning, and the remarkable complexity and range of the generative grammars that are the product of language learning” (Chomsky, 1965: 27–28). The Principles and Parameters (henceforth P&P) framework of generative grammar attempts to fulfill this goal by postulating a specific set of general mechanisms and principles of grammar that are assumed to be part of the innate knowledge a language learner brings to the task of language acquisition – more precisely, the acquisition of a grammar of a human language. To the extent that much of a speaker’s knowledge of his/her language can be derived from this system of mechanisms and principles, the need for language-particular rules of grammar diminishes – thus contributing to an explanation for the rapidity and uniformity of language acquisition. From this perspective, much of the diversity across languages can be viewed as the result of systematic differences in the way the mechanisms and principles apply to the grammars of various languages. These differences appear to fall within a restricted range of options, referred to as parameters. For example, some languages require an overt subject in declarative sentences (e.g., English and French), whereas others allow declarative sentences without overt subjects, presumably where a subject pronoun is deleted (e.g., Spanish and Italian). These options are also assumed to be determined by the language faculty, thus specified as part of Universal Grammar (UG). Within this framework, research on language variation is based on the

working hypothesis that much of the apparent diversity among languages can be reduced to instances of parametric variation. This hypothesis has generated a substantial amount of promising research in the area of comparative grammar (see Jaeggli and Safir, 1989; Freidin, 1991, 1992, 1996; Baker, 1995, 2001; Rizzi, 2000).

It is worth noting that modern comparative grammar has a much more ambitious and wide-ranging goal than its 19-century predecessor. Both are concerned with establishing an explanatory basis for the relationships between human languages. The neo-grammarians of the 19th century were focused primarily on relationships between languages and groups of languages in terms of common ancestry. Contemporary generative grammar is concerned with a theory of grammar that is postulated to be an innate component of the human mind/brain, a faculty that all humans share as part of their genetic identity and that guides the acquisition of language. Thus the theory of grammar establishes the relationship among all human languages – not only those that happen to be related by historical accident (e.g., common ancestry).

The P&P approach to the study of human language came into focus in the late 1970s and has evolved substantially over the past decade as basic assumptions and proposals have been subjected to a critical re-evaluation within the Minimalist Program (see Chomsky, 1995b; Freidin, 1997). Initially, the P&P framework was based on a system of grammatical principles, formulated in terms of fundamental notions of grammatical analysis (e.g., case, agreement, binding, and government). These principles formed the core of modules (e.g., Case and government) that operated within derivations to determine the behavior of syntactic rules, the mechanisms that generate syntactic representations for linguistic expressions. They applied either to derivations (i.e., the application of rules) or to the representations constructed

by derivations. Over the past decade, significant parts of this modular theory of grammar have been eliminated under minimalism. The conditions on rule application that remain are for the most part formulated in terms of principles of efficient computation, while conditions on representations have been recast in terms of economy principles that apply at the two external interfaces: Phonetic Form (PF) at the sensorimotor interface and Logical Form (LF) at the conceptual-intensional interface.

The system of grammatical principles initially proposed as the core of P&P evolved out of the study of conditions on the application of transformations, beginning with Chomsky's work on the A-over-A Principle in the early 1960s (see Chomsky, 1964) and continuing with Ross' work on island constraints (Ross, 1967, 1984) and Chomsky's extension of the conditions framework (Chomsky, 1973). One of the first important breakthroughs in modern comparative grammar came from the work of Kayne (1975) and Quicoli (1976a, 1976b), which demonstrated that certain abstract conditions on the application of transformations, postulated for the analysis of English in Chomsky (1973), also applied to some very different constructions in Romance involving clitics and quantifiers. Another crucial step in the development of the current approach was achieved with the demonstration (Chomsky, 1976) that under Trace Theory the behavior of transformational rules followed from general principles and therefore that transformations could be stated in an optimally general form – essentially as bare elementary transformational operations (e.g., 'substitute α ' or 'adjoin α to β '). Transformational rules in such general form could be viewed as rules of UG (the theory of grammar) rather than as language-specific rules of a particular grammar (or as construction specific rules [e.g., a relative clause transformation]).

The study of filters (conditions on representations) provides another major element of the initial framework (see Chomsky and Lasnik, 1977), one which raises important empirical questions regarding the status of various levels of syntactic representation. This line of research led to the realization of the central role of the notions of Case and government for the theory of grammar (due to Jean Roger Vergnaud, see Rouveret and Vergnaud, 1980), and ultimately to Chomsky's (1981) reformulation and extension of the entire theory, commonly referred to as government and binding (or GB) theory.

Chomsky (1981) related phrase structure theory and the theory of transformations in a new way. Up until this version of the theory of generative grammar, the theory of phrase structure and the theory of transformations had developed more or

less independently: phrase structure rules and transformations were considered independent grammatical mechanisms, both necessary for constructing syntactic representations. By defining a notion of government in terms of the theory of phrase structure and then establishing the major role it plays in the various conditions that determine the behavior of transformations, Chomsky identified a conceptual thread that links the two theories.

During the past decade under the minimalist program, the connection between phrase structure and transformations has been reconstructed so that it is only transformations that construct syntactic representations. The new bare phrase structure theory (see Chomsky, 1995a) radically revises the notion of syntactic derivation in a way that significantly affects the organization and function of grammar under the P&P framework.

The remainder of this article sketches some of the essential parts of the current P&P framework. For an account of the preminimalist version of this framework, see Freidin (1994a).

Mechanisms for Phrase Structure Representations

Under the current P&P framework, syntactic (i.e., phrase structure) representations are constructed by a single transformational operation Merge, an adjunction operation that concatenates two syntactic objects and labels the resulting syntactic object with the syntactic category features of one of the two elements concatenated. Syntactic derivations begin with an array of lexical items selected from the lexicon, a numeration N . Merge then operates on N , constructing a phrase marker containing all the elements in N . In a derivation, lexical insertion results when Merge applies to a lexical item in N . Thus, when Merge applies to a preposition *from* and a NP *my sons* (itself constructed from the merger of two lexical elements), the result is a PP *from my sons* containing a P and a NP as constituents, where *from*, the head of the construction, projects its syntactic category P to label the new construct. The operation is constrained by an Inclusiveness Condition (1), which radically restricts the kind of syntactic objects that can be created in a derivation.

- (1) Inclusiveness Condition: any structure formed by the computation (in particular, PF and LF) is constituted of elements already present in the lexical items selected for N ; no new objects are added in the course of computation apart from rearrangements of lexical properties.
(Chomsky, 1995b: 228)

Condition (1) prohibits the categorial distinction of levels of phrasal projection and the use of indices. Merge is further constrained under the assumption that it is a strictly binary operation and therefore there can only be two immediate constituents of any phrasal category, never more and never less.

Given Merge, every phrase in a phrase structure representation has a unique head, the element that projects its syntactic category features as the label of the phrase. The application of Merge is further constrained by the order in which a head is merged with other constituents. A complement (generally an argument of the head when the head is some form of predicate [e.g., verb, adjective, or derived nominal]) is always concatenated with the head before other kinds of constituents. A specifier is always concatenated with the phrasal projection of the head last and therefore is always an immediate constituent of a maximal phrasal projection. Adjuncts (generally modifiers) are concatenated with a head (when there are no complements) or a phrasal projection of the head after complements and before the specifier.

The application of Merge that concatenates two independent syntactic objects (lexical items from the lexicon or phrases constructed from the concatenation of lexical items) is called External Merge (EM), in contrast to the application of Merge that applies to a single syntactic phrase by adjoining a subphrase of it to the phrase itself (i.e., to its root). This latter application of Merge, which is called Internal Merge (IM), performs movement operations as in the case of simple passive sentences.

(2) Seymour was arrested in Shanghai.

Because the subject NP *Seymour* is interpreted at LF as the object of *arrested*, it is first merged (via EM) as the object of the verb and then moved (via IM) to subject position where it is pronounced (at PF). At LF, the syntactic representation of (1) contains a copy of subject in object position.

(3) Seymour_i was [_{VP} arrested Seymour_i in Shanghai]

(Although indices are prohibited under the Inclusiveness Condition [1], copies here are indicated here via coindexing as a notational convenience.) IM adjoins a copy of the object to the Tense Phrase (TP) *was arrested Seymour in Shanghai* and projects the label T, thereby creating the specifier position of TP.

IM involves only the adjunction operation, i.e. only a single elementary transformational operation. The deletion operation applies to unpronounced copies of syntactic elements only at PF (see Nunes, 2004 for a detailed discussion). It follows that grammatical transformations do not compound elementary operations (Chomsky, 1980). A syntactic element and its

copies form a nontrivial chain. The elements of a chain are distinguished in terms of their contexts (e.g., in [2] where the object *Seymour* is a sister of a verb while the subject *Seymour* is a sister of a TP (*was arrested Seymour in Shanghai*)).

In addition to the movement of NP to the Spec-TP position in passive constructions, IM also displaces the finite auxiliary verb in yes/no questions (4) and direct questions involving an interrogative pronoun (5), as well as wh-phrases in direct and indirect questions.

(4) Was Seymour arrested in Shanghai?

(5) In which city was Seymour arrested?

Example (5) involves three kinds of movement: (a) of an NP (*Seymour*), (b) of a head (*was*), and (c) of a wh-phrase (*in which city*). Each is performed by the same operation IM.

Given that IM is restricted to adjoining a phrase to the root, derivations cannot segregate applications of IM from those of EM, as was done in earlier versions of transformational grammar where movement transformations applied after the construction of an initial phrase marker. Thus in (3), the movement of the NP *Seymour* via IM occurs before the insertion of the complementizer *that* (the head of the Complementizer Phrase [CP]), as well as the verb *believe* and the pronoun *they*, via EM.

(6) They believe [_{CP} that [_{TP} Seymour_i was arrested Seymour_i in Shanghai]]

Because of this, derivations under bare phrase structure theory cannot define a canonical level of D-structure as in previous theories. Therefore, there is no level of D-structure under this theory.

Restricting the application of Merge to the root yields a version of 'strict cyclicity' (Chomsky, 1973; Freidin, 1978, 1999; H. Lasnik, personal communication, 2004), where a phrase that has become a constituent of another phrase cannot be altered by further applications of Merge (either EM or IM).

Constraints on Derivations and Representations

The operation Merge sketched in the previous section will by itself generate deviant constructions and therefore must be supplemented by further constraints to distinguish deviant from nondeviant utterances in a language. As has been demonstrated in research on dozens of languages over the past several decades, these constraints apply generally across languages. Constraints have been formulated in one of two ways, as conditions on the application of rules (i.e., on derivations) or as conditions on the representations constructed by rules. In current work, both kinds of

constraints have been formulated in terms of a notion of computational economy whereby the operation of rules and the representations they generate are optimally efficient in computing the relation between sound and meaning in linguistic expressions. In essence, economy conditions prohibit superfluous steps in derivations and superfluous elements in representations.

Full Interpretation

The fundamental condition on representations, Full Interpretation (FI) (Chomsky, 1986), requires that all elements in the representations at the interface levels, PF and LF, must be fully interpretable. Thus at LF, representations must contain no phonetic material under the assumption that such material cannot be interpreted by the cognitive modules that interface with LF. Similarly, PF representations must not contain any semantic information or syntactic constructs such as nontrivial chains, which cannot be interpreted at the sensorimotor interface.

Given FI, a derivation from N to LF must contain a point where phonetic material is separated from the syntactic representation and transferred to the phonological component of the grammar that constructs PF representations. This point, called Spell-Out, roughly corresponds to S-structure in previous analyses if there is only one point in a derivation. However, if there is multiple Spell-Out (Uriagereka, 1999; Chomsky, 2001), then classical S-structure cannot be constructed.

Applied at LF, FI eliminates constructions with superfluous arguments. For example, Merge could construct the following deviant example (7) in addition to the nondeviant examples (8a, 8b).

(7) *John gave Bill a book to Mary.

(8a) John gave Bill a book.

(8b) John gave a book to Mary.

The verb *gave* will assign argument functions (θ -roles) to the three NPs in both (8a) and (8b), but only three of the four NPs in (7). It can assign the indirect object θ -role to either *Bill* or *Mary*, but not to both. Therefore one of these NPs will not have a θ -role at LF, in violation of FI.

Case phenomena in languages are also governed by FI under the assumption that Case features are superfluous (hence uninterpretable) at both LF and PF and therefore have to be eliminated in the course of the derivation from N to LF. This can be illustrated with the following paradigm.

(9a) It is likely that he will graduate in June.

(9b) He is likely to graduate in June.

(9c) *It is likely he/him to graduate in June.

In (9a), the nominative Case pronoun *he* is the subject of the verb *graduate* and the matrix subject is the pleonastic element nonreferential *it*, which has no θ -role. The predicate adjective *likely* is a one-place predicate that assigns its single θ -role to the clausal complement *that he will graduate in June*. In (9b) the clausal complement of *likely* is infinitival rather than finite and the NP that is interpreted as the subject of the infinitival clause (*he*) has moved via IM to the subject position of the main clause. This movement is from a position that is assigned a θ -role to one that is not. This movement is obligatory because when it does not occur, as in (9c), the result is deviant. The difference between (9a, 9b) and (9c) is that the pronouns in the former occur in a position where they are licensed, whereas neither pronoun in the latter is licensed in that position. Once a Case feature is licensed it can be eliminated from the derivation and therefore will not show up at LF or PF. If it is not licensed, then it shows up at LF and PF in violation of FI. This analysis generalizes to overt NPs that do not show overt morphological Case (e.g., substitute the name *Adam* for the pronouns in [9] and the same result obtains), and therefore concerns a notion of abstract structural Case, which plausibly plays no role at PF (in contrast to overt morphological Case).

This analysis generalizes to the analysis of simple passives as discussed above. Thus compare (2) with the deviant (10).

(10) *It was arrested Seymour in Shanghai.

The pleonastic nonreferential *it* occurs in a non- θ -position and is licensed for Case as the subject of a finite clause. In contrast, *Seymour* occurs in a θ -position. Assuming that the reason the NP *Seymour* moves in (2) is to get to a Case-licensed position and thereby eliminate its Case feature, then the object position of a passive predicate must not be licensed for Case, in which case the NP *Seymour* violates FI at LF and PF because it still has whatever abstract Case feature it brings from the lexicon.

The abstract structural character of Case licensing can be more sharply illustrated in languages with more complex Case phenomena than English. Consider the following paradigm from Icelandic.

- | | | | |
|-------|------------|-----------------|-----------------|
| (11a) | Jóni | batnaði | veikin |
| | John-DAT | recovered-from | the-disease-NOM |
| (11b) | Ég tel [TP | Jóni hafa | batnað veikin] |
| | I believe | John- to | recovered- the- |
| | | DAT have | from disease- |
| | | | NOM |
| (11c) | [CP að [TP | PRO | batna |
| | | PRO-DAT | to-recover-from |
| | | veikin]] | er venjulegt |
| | | the-disease-NOM | is usual |

- (11d) *<sub>[CP að [TP Jóni batna
John-DAT to-recover-from
veikin]] er mikilvægt
the-disease-NOM is important</sub>

Although the verb *batna* ('recover from') selects a dative subject as a lexical property, (11c) illustrates that the null subject PRO can satisfy this requirement even though it has no phonetic content. Yet as (11d) shows, lexical satisfaction of the Case requirement is not sufficient since the lexically Case-marked NP cannot have phonetic content. The subject of the infinitive in (11d) is not structurally licensed for Case, in contrast to (11b) where the dative NP occurs in an 'exceptional Case-marking' context governed by the matrix verb *tel*. In (11b), the element that determines the actual morphological Case is distinct from the element that licenses abstract Case. Such examples demonstrate the need to distinguish morphological Case assignment from abstract structural Case licensing (see Freidin and Sprouse, 1991). Both requirements must be satisfied in order to remove uninterpretable Case features from the derivation.

The FI account of obligatory movement can be extended to wh-movement (i.e., movement to Spec-CP position) under the assumption that the head C contains a formal syntactic feature, which is uninterpretable and therefore must be eliminated in the course of the derivation. In (12), for example, the wh-phrase moves from a Case-marked object position to Spec-CP, which is Case-less.

- (12a) Which books did you borrow?
(12b) [_{CP} [_{NP} Which books]_i did_j [_{TP} you did_j borrow
[_{NP} which books]_i]]

It is also a movement from a θ -position to a non- θ -position. Since the movement must be overt (i.e., show up in PF), the formal feature involved must be uninterpretable at both LF and PF and therefore must be eliminated before Spell-Out.

In some languages (e.g., Chinese), wh-phrases do not move in overt syntax. Instead they move after Spell-Out i.e. covertly in LF (see Huang, 1981/1982). The covert movement of wh-phrases is also motivated by FI under the assumption that a wh-phrase constitutes a quasi-quantifier and as such must bind a variable created by movement at LF. Otherwise the quantifier without a variable to bind, a case of vacuous quantification, is uninterpretable. Presumably, Chinese lacks the formal feature that forces overt wh-movement.

Agreement features on verbs are also formal syntactic features that are considered uninterpretable at PF and LF and therefore can trigger a violation of FI unless they are eliminated before Spell-Out. If the agreement features on finite T enter the derivation

unvalued and are then valued by the agreement features of the head of Spec-TP, then unless an NP is merged in that position, the agreement features of T remain unvalued and violate FI at the interfaces. Thus it follows from FI that a finite clause must have a syntactic subject, even in languages where the subject is absent at PF. Thus agreement features on verbs can also be considered as a trigger for NP-movement.

Whether this analysis can be extended to cases of improper movement as in (13) is not as clear.

- (13a) *He is likely will graduate in June.
(13b) *_{[TP he_i is likely [_{TP} he_i will graduate in June]]}

When the pronoun *he* is first merged in the complement clause, it values the agreement features of the complement T. It is generally assumed that once a NP values the agreement features of one T, it cannot value the agreement features of another. Assume this to hold whether or not the NP is frozen in place after agreement applies. Then the agreement features on matrix T in (13) will remain unvalued, in violation of FI.

Not all improper movement cases involve a violation of FI. In (14), movement is from the subject of a finite clause to the subject of an infinitival clause.

- (14a) *It is easy he to believe has written a book.
(14b) *it is easy [_{TP} he_i to believe [_{TP} he_i has written
a book]]

The pronoun *he* moves from a Case-marked to a Case-less position. The Case features of the pronoun and the agreement features of the finite T are all eliminated from the derivation, so the result does not violate FI. However, notice that the uninterpretable Case and agreement features were eliminated prior to the movement of the pronoun.

One way to account for the deviance of (14) is to prohibit movements between two θ -positions by restricting the number of θ -roles a chain may have to one (see Freidin, 1978; Chomsky, 1981). An alternative is to prohibit the movement itself on the grounds that it is unmotivated by any grammatical factor, in contrast to legitimate phrasal movements. Since the pronoun *he* is both licensed for Case and assigned a θ -role in its initial position as subject of the complement of *believe*, there is no motivation for it to move further. From this perspective, movement is viewed as a 'last resort' to save a derivation from violating FI. Any movement that fails to meet this criterion is superfluous and therefore ruled out on general grounds of computational efficiency.

Locality of Movement

In addition to constraints on when and where a phrase must move and when it may not move, must also specify 'how far' a movement can be. Although

IM has the capability of moving a constituent indefinitely far away from its EM position, actual movement phenomena in languages demonstrate that certain syntactic boundaries may not be crossed; in effect, IM may not move a constituent 'too far' away. Thus movement operations are bounded within a particular syntactic domain. Compare, for example, the long-distance *wh*-movement in (9a), where the *wh*-phrase is interpreted as the verbal object in a clause (analyzed here as a Tense phrase (TP) contained in a Complementizer phrase [CP]) that is itself embedded in three other clauses, to the much shorter but impossible movements in (15b) and (15c).

- (15a) $[_{CP} \text{ who}_i \text{ did } [_{TP} \text{ you say } [_{CP} \text{ that } [_{TP} \text{ Mary knows } [_{CP} \text{ that } [_{TP} \text{ Bill told Sam } [_{CP} \text{ that } [_{TP} \text{ Rachel admires who}_i]]]]]]]]]$
- (15b) $*[_{CP} \text{ who(m)}_i \text{ did } [_{TP} [_{NP} \text{ your interest in who(m)}_i] \text{ surprise Mary}]]]$
- (15c) $*[_{CP} \text{ what}_j \text{ did } [_{TP} \text{ John wonder } [_{CP} [_{PP} \text{ to whom}]_i \text{ } [_{TP} \text{ Bill gave what}_j \text{ } [_{PP} \text{ to whom}]_i]]]]]$

In contrast to (15a), the movement in (15b) is intra-clausal rather than interclausal and the movement in (15c) only crosses one clause boundary instead of many.

The boundedness of IM can be accounted for in terms of a general principle of grammar that designates certain categories as bounding categories and sets a limit for bounding categories that may be crossed in a single-movement operation. This limit is fixed in UG at one bounding category. Two syntactic positions are said to be subjacent to one another if they are separated by no more than one bounding category. The principle for bounding, the Subjacency Condition, has the effect of prohibiting a single movement that crosses more than one bounding category.

(16) Subjacency Condition

Movement can only be to a subjacent position.

This principle can be formulated as a condition on chain links, in which case it constitutes a condition on representations rather than a condition on the application of rules (see Freidin, 1978; Browning, 1991). Alternatively, it has been argued that the Subjacency Condition must be formulated as a condition on the application of the movement rule (see Lasnik and Saito, 1984, 1992). Assuming the bounding categories for Subjacency are NP and TP, (16) rules out (15b) and (15c). To account for (15a), it is assumed that *wh*-movement operates locally when it can, so that *who* moves successively through each of the intervening Spec-CP positions, thereby avoiding a Subjacency violation. The condition applies more generally to

many other constructions involving movements across two NPs or across two TPs (see Freidin, 1992 for discussion and references). As a condition on representations, it applies at S-structure (see Freidin and Lasnik, 1981 for discussion) and therefore is incompatible with the multiple Spell-Out analysis mentioned above.

Bounding effects appear to vary across grammars. In some idiolects of Italian, it is possible to extract a relative pronoun out of an indirect question (see Rizzi, 1982).

- (17) $\text{il mio primo libro, } [_{CP} \text{ che}_i \text{ } [_{TP} \text{ credo } [_{CP} \text{ che}_i \text{ che } [_{TP} \text{ tu sappia } [_{CP} [_{PP} \text{ a chi}]_j \text{ } [_{TP} \text{ ho dedicato che}_i \text{ } [_{PP} \text{ a chi}]_j]]]]]]]$ *me è sempre stato molto caro*
'my first book, which I believe that you know to whom I dedicated, has always been very dear to me'

The sentence is well formed even though the movement between two trace positions crosses two TPs. This suggests that TP is not a bounding category in this idiolect of Italian. Nonetheless, a bounding effect occurs in Italian when a single movement of *che* crosses two CPs, as in (18).

- (18) $*\text{il mio primo libro, } [_{CP} \text{ che}_i \text{ } [_{TP} \text{ so } [_{CP} [_{PP} \text{ a chi}]_j \text{ } [_{TP} \text{ credi } [_{CP} \text{ che}_i \text{ che } [_{TP} \text{ abbia dedicato che}_i \text{ } [_{PP} \text{ a chi}]_j]]]]]]]$ *me è sempre stato molto caro*
'my first book, which I know to whom you believe that I dedicated, has always been very dear to me'

If CP is taken as a bounding category for this idiolect of Italian, then the second and final movement of the relative pronoun *che* violates Subjacency. Similar phenomena pointing to the same conclusion can be found in French and Spanish (see Sportiche, 1981 and Torrego, 1984). Thus the choice of TP vs. CP as a bounding category for Subjacency constitutes one parameter of UG. If both TP and CP are chosen as bounding categories, then Subjacency would prohibit interclausal *wh*-movement. Some languages (e.g., Russian) prohibit this kind of *wh*-movement, a fact that would follow from bounding theory if both TP and CP were bounding categories for Subjacency in these languages.

The Subjacency analysis remains the most general and perhaps the clearest account of syntactic island phenomena (i.e., construction from which the movement of constituents is prohibited). However, it may well be that the Subjacency Condition constitutes a false generalization, as have several other important proposals in the history of generative grammar. Moreover, the stipulation of bounding categories is essentially descriptive rather than explanatory and the principle itself is not easily interpreted in term of economy.

More recently, other analyses have been proposed that cover some of the empirical range of the Subjacency Condition. Chomsky (1993) proposes an economy principle that derivations involve the shortest steps (the Minimal Link Condition; see also Chomsky, 1995b), which prohibits (15c) on the grounds that the movement of *what* to the matrix Spec-CP is not the shortest movement possible because the movement from Spec-CP to Spec-CP is shorter. Chomsky (2001) proposes that subparts of derivations (phases) become inaccessible to further computation because they are transferred to PF and LF when complete. Details aside, under this proposal, *what* in (15c) would be inaccessible for movement because it is not at the edge of the CP phase. The proposals are problematic given that the movements they prohibit for English appear to be possible in several Romance languages (e.g., as in [17] above). Whether there is an alternative to the Subjacency analysis of locality with the same empirical coverage remains to be determined.

Binding Theory

Movement is not the only process that creates relations between pairs of positions within a sentence. Anaphoric expressions also create such relations via the interpretive link to their antecedent. Languages contain two types of anaphoric expressions: those that require the presence of an antecedent in the same sentence, called bound anaphors (i.e., reflexive pronouns and reciprocal expressions, henceforth anaphors), and pronouns (including anaphoric epithets like *the bastard*), which can occur in a sentence without an antecedent. Binding theory is concerned in part with the conditions under which anaphors and pronouns can be linked to an antecedent. (For more detailed discussion see Freidin, 1986; Lasnik, 1989; Koster and Reuland, 1992; and Chomsky and Lasnik, 1993.)

Bound Anaphors Formally, an antecedent binds an anaphoric expression when the anaphor is a constituent of the phrase that is merged with the antecedent (i.e., its sister). The paradigm for anaphors in (19) illustrates that all possible binding relations are not licit. (Again coindexing is used here and in what follows as a notational convenience.)

- (19a) simple sentence
 we_i help each other_i
 (19b) finite clause complement:
 (19b.i) $*we_i$ expect [_{CP} (that) [_{TP} each other_i
 will win]]
 (19b.ii) $*we_i$ expect [_{CP} (that) [_{TP} Mary will
 help each other_i]]

- (19c) infinitival complement:
 (19c.i) we_i expect [_{TP} each other_i to help Mary]
 (19c.ii) $*we_i$ expect [_{TP} Mary to help
 each other_i]

While all the anaphors in (19) are bound, only those in (19a) and (19c.i) are properly bound. Proper binding of anaphors falls under a principle of grammar, referred to as Principle A of the binding theory, which is given schematically in (20).

- (20) Principle A: an anaphor must be antecedent-bound in a local domain δ .

(20) constitutes a principle of UG which, by specifying the local domain δ , is instantiated in the grammar of a particular language as binding condition A.

The local domain for anaphors in English is the domain of an accessible SUBJECT, where SUBJECT stands for a syntactic subject or the agreement element associated with the head of finite TP (given that specifier-head agreement between a syntactic subject and the head T is mandatory in finite clauses). Any syntactic subject is accessible to an anaphor if it binds the anaphor. Thus (19a) and (19c.i) satisfy Condition A because the only accessible subject in each example is the main clause subject to which the anaphor is bound. In (19b.ii) and (19c.ii), the complement subject is accessible to the anaphor, but the anaphor is antecedent-free (i.e., not bound by an antecedent) in the domain of this 'subject'. Therefore, these examples violate Condition A. In (19b.i), the agreement element of the sentential complement constitutes an accessible SUBJECT and in that domain the anaphor is antecedent-free in violation of Condition A. (The precise formulation of the local domain δ for English is somewhat more intricate; see Chomsky, 1986; Freidin, 1986, 1992 for details.)

Cross-linguistically, we find some variation in the local domain δ for Condition A. In Korean, for example, the binding domain for reciprocals is that of any c-commanding NP. Thus within a single clause, a direct object may create a binding domain for the object of a PP in VP, as illustrated in (21) (from Hong, 1985).

- (21) kitil-i [_{NP} John-kwa Mary]-lil
 they-NOM John and Mary-ACC
 sero-eke sogehetta
 each other-to introduced
 they_i introduced [_{NP} John and Mary]_j to each
 other_{*i,j}

In the corresponding English example, either the subject or the direct object may be the antecedent of the reciprocal. Hence the binding domain for reciprocals in Korean is more restricted than that of English. This indicates that the binding domain for Principle

A is subject to parameterization. (See Freidin, 1992: Chap. 7 for a more detailed discussion of parameterized binding.)

Pronouns In contrast to bound anaphors, which must be antecedent-bound within a certain domain, pronouns cannot be bound within certain domains. The paradigm for pronoun binding corresponding to (19), given in (22), illustrates a complementarity between bound anaphors and bound pronouns where a bound anaphor can occur, a bound pronoun may not.

- (22a) simple sentence
 *the politician_i voted for him_i
 (22b) finite clause complement:
 (22b.i) Clara_i expects [_{CP} (that) [_{TP} she_i will win]]
 (22b.ii) Clara_i expects [_{CP} (that) [_{TP} Sam will help her_i]]
 (22c) infinitival complement:
 (22c.i) *Clara_i expects [_{TP} her_i to help Sam]
 (22c.ii) Clara_i expects [_{TP} Sam to help her_i]

Thus pronoun binding is accounted for by a principle of grammar complementary to Principle A, referred to as Principle B of the binding theory.

- (23) Principle B: a pronoun must be antecedent-free in local domain δ .

As with Principle A, Principle B is instantiated in the grammar of a particular language as binding condition B by specifying the local domain δ . As with anaphor binding, this domain varies across languages. For example, pronoun binding in the Icelandic sentence corresponding to (22c.ii) is not possible.

Given the complementarity of anaphors and bound pronouns illustrated in (19) and (22), it would appear that the specification of the local domain for pronoun binding is identical to that of anaphor binding. Although this complementarity holds for binding within TP and across TP boundaries, it collapses with respect to binding across NP boundaries, as examples (24–25) illustrate.

- (24a) they_i never discuss [_{NP} each other's_i work]
 (24b) they_i never discuss [_{NP} their_i work]
 (25a) every man_i heard [_{NP} a story about himself_i]
 (25b) every man_i heard [_{NP} a story about him_i]

These examples show that the domain statement for Condition B in English cannot be identical to that of Condition A, since if it were, then (24b) and (25b) should be unacceptable on a par with (22a) and (22c.i), contrary to fact.

These examples show that NP constitutes a binding domain for pronouns and the paradigm in (22) shows that TP constitutes another binding domain with one

exception – (22c.i) – where the matrix verb governs the complement subject across TP. One property that NP and TP share in common is that they both constitute domains in which predicates (e.g., verbs and derived nominals) may discharge their θ -roles (θ -domains, or complete functional constructs [in the terminology of Chomsky, 1986]). Example (22c.i) shows that the binding domain for pronouns is not the minimal θ -domain containing the pronoun, but rather the minimal θ -domain of the matrix verb, which is implicated in Case licensing of the pronoun. (For further discussion of the representation and interpretation of pronoun binding, see Lasnik, 1989.)

Universally, a pronoun cannot be anaphoric on an antecedent when it is in a structural binding relation to the antecedent (i.e., it is merged with a phrase that contains the antecedent), as in (26).

- (26) *she_i expects [_{CP} (that) [_{TP} Sam will help Clara_i]]

Example (26) can never be interpreted as a sentence about two people. Note that this is not a matter of the pronoun preceding its antecedent since (27) has the same linear property but not the same interpretive restriction.

- (27) His professor praised John in class.

Example (27) can be interpreted as a sentence about two people as well as a sentence about three. The constraint that accounts for the impossibility of the interpretation represented in (26) is designated in the literature as Principle C.

Conclusion

The material covered in this article is merely a sketch of some of the central topics being investigated within the principles and parameters framework. Ongoing research extends the empirical coverage of various subtheories, including parametric variation across languages. Current work also explores a number of promising alternative analyses for various parts of the theory. As in any area of rational inquiry, no assumption is immune to critical inquiry.

For further discussion of these and other topics within this approach to generative grammar, see van Riemsdijk and Williams, 1986; Lasnik and Uriagereka, 1988, 2005; Lasnik, 1999, 2003; Freidin, 1992; Epstein and Hornstein, 1999; and Epstein and Seely, 2002 among many others. Many of the topics under investigation have a long and rich history in generative grammar of the past half century: see Newmeyer, 1986; Freidin, 1994b for an historical account.

The principles and parameters framework of generative grammar attempts to establish the common biological basis for all the world's languages.

The current work in comparative grammar illuminates the human language faculty as an intricate computational structure of the human mind that is unique to the genetic endowment of our species. In this way work in contemporary comparative grammar continues to make a major contribution to the emerging cognitive science enterprise.

Private Language Argument

D Byrne, University of Birmingham, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

The private language argument is the strand of Ludwig Wittgenstein's later work (in particular, 1953: §§243–315) in which he endeavored to demonstrate the impossibility of a language that only one person could understand – or, at any rate, as Wright (1986) suggested, that only one person could have *reason to believe* he or she understood. Early commentators, although divided over the argument's cogency, regarded it as perhaps the most powerfully subversive weapon in Wittgenstein's armory. Fashions have changed, however, and nowadays few philosophers seem to agree even on so much as whether the argument exists and, if it does, how it works. Critics satirize the legendary argument as a kind of perpetually elusive 'Philosopher's Stone' of woolly-minded pragmatism, and even Wittgensteinians tend nowadays to downplay the significance of any single *argument*, preferring to emphasize themes expounded by Wittgenstein in the surrounding passages (see Hacker, 1986; McDowell, 1989; McGinn, 1997).

The Argument's Target

Wittgenstein's interest is probably not linguistic *per se*: his intention is to attack a general conception of mind, usually labeled Cartesian. According to this picture, introspection affords thinking subjects an especially direct, observational access to their own mental states, whereas their access to the mental states of others is indirect and theoretical – a matter of inference from their behavior. This conception seems particularly compelling in regard to sensations and other phenomenal experiences.

Wittgenstein invites us to consider a subject – let us call him *PD* (Private Diarist) – who undertakes to name various types of sensations and record their occurrences in a diary. Cartesianism would seem to suggest that, to inaugurate names of sensation-types in this way, it would suffice for *PD* simply to "speak, or write the sign down, and at the same time ...

concentrate ... attention on the sensation – and so, as it were, point to it inwardly" (Wittgenstein, 1953: §258). The Cartesian conception also seems to suggest that subjects other than *PD* could have no reason to believe they understood these terms, so that a language containing them would be *private* to *PD* in the sense intended. By arguing that such a language is impossible, then, Wittgenstein attacks the Cartesian conception of mind that underpins it.

The Cartesian conception continues to dominate our intuitive, 'pretheoretical' view – at least of those mental states that enjoy a distinctive phenomenology. This alone ensures that it really matters whether there is a cogent private language argument. However, before addressing that question, it is also worth briefly considering which contemporary theories – of philosophy, psychology, linguistics, and so on – are threatened by the argument. Wittgensteinians frequently bemoan the widespread infection of mainstream theory in these disciplines by Cartesianism, but although there are reasonable general grounds for this complaint, it is actually quite difficult to find theories that are threatened by the private language argument *per se*.

The 'representational theory of mind' that underwrites much recent work in cognitive science and linguistics might seem the most obvious candidate. Indeed, Fodor (1975) has provocatively placed himself on the firing-line on its behalf. According to the representational theory, cognition involves the manipulation of symbols that, like linguistic expressions, enjoy representational contents, yet that are private in the sense that those contents are not determined by anything like public conventions or criteria. As is discussed below, there is an interpretation of the private language argument that would place the notion of contentful symbols that are private in this sense in its sights, but it is not the most plausible interpretation. Meanwhile, we can already see that there is no *prima facie* tension between the representational theory and the argument's conclusion. For one thing, Fodor did not suppose that representations' contents are conferred by anything like acts of introspective ostension. Even more to the point,

an advocate of the representational theory is entitled to insist that there could be good (empirical) reasons to suppose that two subjects enjoyed representations with the same content (and so to suppose that, in a sense, subjects ‘understood’ the same representations).

Much more vulnerable to challenge are the ‘direct reference’ theories of ‘phenomenal concepts’ recently defended by Loar (1997), Chalmers (2003), and others. The key idea here is that subjects enjoy concepts of the phenomenal qualities of their own conscious experiences whose contents are exhausted by their references. Some of these theorists suggest that such concepts are inaugurated through acts of introspective demonstration, and given the distinctive semantics they are proposed to enjoy, it is difficult to see how such concepts could fail to be private in something like the sense at issue here.

Supplementary Strands

Most of Wittgenstein’s remarks in the passages generally considered to contain the private language argument do not directly address the issue identified above as central, but instead are concerned with the meanings of expressions used in public languages to talk about sensations and other mental states.

Wittgenstein held quite generally that understanding an expression is a matter of knowing and following rules that regulate how it is used in various language-involving activities – ‘language games’ – in which speakers participate. One thing Wittgenstein did in these passages is to emphasize the third-person uses of (public language) sensation terms. Understanding words like ‘toothache’ and ‘pain’ involves, *inter alia*, knowing what kinds of behavioral criteria sanction their third-person attribution. Therefore, at any rate, that understanding cannot be just a matter of demonstrative first-person acquaintance with pains, as a thoroughgoing Cartesian might assume. Of course, a Cartesian might reply by conceding the point about public language sensation terms, but insisting nonetheless on the possibility of distinct, privately inaugurated terms lacking third-person applications altogether.

Elsewhere in these passages, Wittgenstein made characteristic proposals to the effect that what seem superficially to be assertions may in fact be speech acts of other kinds: warnings, exclamations, ‘performatives,’ etc. One example is his suggestion that utterances involving (public language) sensation terms can be used to express sensations, rather than to describe them: “Here is one possibility: Words are connected with the primitive, the natural, expressions of the sensation and used in their place” (§1953: 244). Considering sentences that might seem to articulate

the most fundamental features of sensations, such as ‘Sensations are private,’ Wittgenstein suggested that these are used to express the rules that govern the terms involved, rather than to make substantial assertions: ‘Sensations are private’ is comparable to “One plays patience by oneself” (1953: §248). These points are interesting and important; however, even if Wittgenstein is right that apparently indicative sentences featuring public language sensation terms can have these nonassertoric uses, this does not refute the Cartesian’s basic belief in the possibility of a different language, in which he can privately make assertions about his own sensations.

Rules and Communities

Why, then, does Wittgenstein repudiate the possibility of a private language? His basic contention seems to be that a subject who undertook to inaugurate names for sensation-types he experiences by defining them through introspective demonstrations would not succeed in imbuing the names with genuine meaning – even ‘for himself.’ Yet, why not?

One point Wittgenstein makes is that, normally, inaugurating a new name requires a lot of background “stage-setting” (1953: §257) of a kind unavailable here. For example, parents’ ability to name their children depends on a background of conventions concerning the roles played by persons’ names in the various language-games in which they feature. However, the Cartesian is likely to respond that PD might instate ‘private conventions’ of suitable kinds. Whether this is possible is really just the question at issue, so Wittgenstein owes more of an argument than is provided by a catalogue of differences between the private and public cases.

Just such an argument seems to be offered in this famous passage:

I impress on myself the connexion between the sign and the sensation. – But ‘I impress it on myself’ can only mean: this process brings it about that I remember the connexion *right* in the future. But in the present case I have no criterion of correctness. One would like to say: whatever is going to seem right to me is right. And that only means that here we can’t talk about ‘right’ (1953: §258).

Suppose that PD experiences a sensation and attempts demonstratively to label the type of sensation it represents as ‘S.’ If ‘S’ is to be genuinely meaningful, there must be a difference between PD’s later (1) correctly applying it to a sensation that really is of the same type as the first, and his (2) misapplying it by mistakenly applying it to a sensation that is really of a different type. Wittgenstein’s contention seems to be that no such distinction can be sustained in this case,

because PD has no ‘criterion of correctness’ to go on independent of his own inclinations. The question the Cartesian will want to press, however, is precisely why such a criterion must be in this way independent. The argument should not be based on an assumption that PD’s judgments about whether a certain sensation is of the same phenomenal kind as the one he previously labeled ‘S’ are *unreliable* – that is on a general skepticism about PD’s memory – for such an assumption would, once again, simply beg the question against the Cartesian.

As we saw above, Wittgenstein holds that linguistic understanding involves knowledge of rules regulating the use of terms. A striking feature of such knowledge seems to be its generality, because understanding a term involves the ability to use it in many different kinds of situations. He is particularly preoccupied with the question of how the contents of rules can be in this way general and, yet at the same time, apparently constitute objects of conscious awareness: things that speakers can “grasp in an flash” (1953: §138). Some commentators maintain that Wittgenstein proposes to resolve this tension by, in effect, denying that meanings really are objects of conscious awareness and by holding that a speaker’s linguistic understanding is in the end simply a matter of her using terms in the same ways as other members of her linguistic community. According to this view, the patterns of use upon which members of a speech community converge engender ‘criteria’ of correct use that are in large measure independent of the judgments of individual members. Thus, in this picture, linguistic expressions generally are governed by criteria of correctness independent of individual speakers’ impressions, and Wittgenstein’s injunction that ‘S’ would be meaningful only if – *per impossible* – it could be so governed is just a special case of this general doctrine. Notice furthermore that if representation in general rests on this kind of communal convergence, then the private language argument threatens the representational theory of mind, as well as the Cartesian position discussed here.

The trouble with this interpretation of the private language argument is that the general ‘communitarian’ conception of rule following and meaning on which it rests is implausible. Moreover, commentators generally reject its attribution to Wittgenstein. (Wright (1980) explored the communitarian interpretation in detail and offered some defense. Kripke’s (1982) notorious interpretation may be considered a version of the communitarian one, its distinctive spin being the meaning-skepticism that Kripke also attributed to Wittgenstein. See Baker and Hacker (1984) and McDowell (1984) for forceful arguments against both the view and its attribution to Wittgenstein).

Radical Evidence-Independence and the ‘Theory Response’

I have argued that, although the ‘supplementary strands’ of Wittgenstein’s discussion highlight numerous important contrasts between ordinary public language sensation terms and the names that PD undertakes to introduce, these considerations do not motivate Wittgenstein’s contention that PD *cannot* imbue the latter with genuine meaning. There is an influential conception of rule following and meaning that does provide such a motivation, but it is widely rejected, both as a theory of meaning and an interpretation of Wittgenstein. In this final section, I describe a different way to defend Wittgenstein’s insistence that PD cannot inaugurate a meaningful term in the manner considered.

The crucial issue is that the Cartesian conception seems to imply that PD’s beliefs about whether a current sensation is of the type he earlier labeled ‘S’ could be correct or incorrect, even if no evidence bearing on the matter were available. Commitment to this possibility implies an extremely strong form of realism or ‘evidence-independence’ both about the sensations at issue and also (this is often overlooked) the intention – the baptismal ‘undertaking’ – in terms of which PD is proposed to have inaugurated ‘S’.

Advocates of the argument are often accused of resting illicitly on a verificationist and/or behaviorist assumption, and it is true that verificationism (in respect of mental states) and behaviorism are at odds with this radically realist picture. However, it is not necessary to subscribe to either of those views to feel uncomfortable about the degree of evidence-independence to which the Cartesian realist seems committed here. The Cartesian holds not only that there may be truths about whether a sensation that PD has is of the type he earlier labeled ‘S’, for which there is no conclusive evidence, but also that such truths may obtain in the absence of any evidence whatsoever – even of the entirely nonbehavioral, introspective kind associated with the Cartesian notion of privileged introspective access. Wittgensteinians, such as Wright (1991), have argued forcibly that this degree of evidence-independence is more than our ordinary psychological notions – particularly those of intentions – can bear. Consider, for example, the idea that a subject *believes that goldfish are highly dangerous*, even though after careful reflection, she is convinced that she does not believe that, and even though all of her behavior – recorded over as long a temporal interval and in as much detail as you like – demonstrates no inclination whatsoever to avoid goldfish, to protect her loved ones from them, etc. If this idea seems

absurd, then it looks as though we should also reject the radical evidence-independence of baptismal 'undertakings' to which the Cartesian seems committed.

Actually though, there is a way to question whether the Cartesian needs to be quite as rampantly realist as this. I have been working with the assumption that the only 'criterion of correctness' PD can apply is his own introspectively grounded impression of whether a current sensation is like the one he baptized 'S.' Yet, suppose PD has reflected on his sensations enough to formulate (in his private language) theories about them, concerning, for example, which types of sensations tend to cooccur during given temporal intervals and which not. Blackburn (1984) and others have suggested that commitment to well-confirmed theoretical hypotheses of this kind could give PD reason to disregard a phenomenal appearance at odds with it, just as a scientist might disregard the appearance of an experimental result at odds with accepted theory. If this is right, then PD might reasonably judge that an earlier application of 'S' to a sensation had been in error, even though his impression at the time had been that it was just like the one he initially associated with the term. This 'fallibilist' Cartesian can hold that there can be evidence of (sincere) misapplication (or indeed, of (sincere) correct application) of terms in a private language and so avoid commitment to the degree of evidence-independence described above.

The 'argument from radical investigation-independence' is the most formidable version of the private language argument, and the 'theory response' represents the most promising rejoinder. However, the response has not been developed in the kind of detail a conclusive adjudication would require. Wright (1986) delved deeper than most, arguing that the response depends on the assumption that PD's 'theory' satisfies various formal constraints that theories codifying patterns of cooccurrence and non-cooccurrence of sensations of given types over given temporal intervals are very unlikely to satisfy. However, the Cartesian is likely to hope that even if Wright is correct about theories of this particular, rather rarefied sort, a more general integration of private phenomenal concepts into a subject's thinking might engender a structure that does satisfy those constraints. (For some recent critical reaction to Wright (1986), see Bain (2004) and Byrne (in preparation).) As things stand then, the issues surrounding Wittgenstein's famous argument remain almost as open as they were a half-century ago.

Proper Names: Philosophical Aspects

M Reimer, University of Arizona, Tucson, AZ, USA

What Are Proper Names?

Intuitively, we can think of proper names as linguistic ‘tags.’ In the terminology of John Stuart Mill (1843), although proper names denote, they do not connote; they do not ‘imply attributes.’ For instance, when a speaker uses the name ‘Kripke’ to refer to the famous philosopher, he or she does not thereby imply anything about Kripke; he or she simply refers to the man. This intuitive construal of proper names is helpful insofar as it provides a rough idea of what philosophers are theorizing about when they claim to be theorizing about ‘proper names.’ Nevertheless, Mill’s characterization is not uncontroversial for reasons discussed later.

Two Central Issues: Meaning and Reference

Proper names raise two central philosophical questions. First, what is the meaning of a proper name? What (in other words) is its contribution to the meanings of the sentences in which it occurs? ‘Vienna’ presumably contributes something to the meaning of ‘Vienna has great pastries.’ What exactly does it contribute? Second, how does a proper name refer? How (in other words) does it ‘attach to’ its bearer? When I say that ‘Rumsfeld is in the news again,’ the subject term of the sentence I utter ‘picks out’ a certain Donald Rumsfeld, thereby enabling me to talk about him. What makes this possible? Some philosophers (including Frege, 1892/1962) believe that an answer to the first question will yield an answer to the second. Let us therefore begin with the first question.

Theories of Meaning

Since the rise of analytic philosophy in the early decades of the 20th century, two theories of meaning have dominated the literature on proper names: Millian and description theories. Description theories are motivated largely by their ability to handle the very sorts of cases that prove problematic for Millian theories. Let us therefore begin with the latter.

Millian Theories

According to Millian theories, the meaning of a name is simply its bearer. In other words, a name contributes its bearer (and only its bearer) to the meaning of any sentence in which it occurs. Thus, Vienna itself is what

‘Vienna’ contributes to the meaning of ‘Vienna has great pastries.’ Such theories are called ‘Millian’ after John Stuart Mill, who (as noted previously) famously claimed that proper names denote but do not connote. Thus, insofar as such expressions can be said to ‘mean’ anything at all, they mean what they denote.

Contemporary Millians, and philosophers of language generally, often prefer to talk in terms of the ‘proposition expressed,’ where this is understood as meaning (roughly) what is said by the literal utterance of a sentence. Thus, ‘Vienna’ is said to contribute Vienna itself to the proposition expressed by any sentence in which that name occurs. Vienna is said to be the ‘semantic value’ of the name. In this way, Millians can avoid the odd-sounding claim that names ‘mean’ what they refer to. Names do not ‘imply attributes’; they do not ‘connote.’ In that sense of meaning, names do not mean anything at all. Their semantic function is simply to denote and their denotations are what they contribute to the proposition expressed. Recent advocates of Millianism, both of whom talk in this vein, include Nathan Salmon (1986) and Scott Soames (1987).

A central virtue of Millianism is its intuitive plausibility. Intuitively, ‘Dick Cheney’ refers to Dick Cheney without thereby characterizing him in any way. This taglike feature of proper names appears to be what distinguishes such expressions from much of the rest of meaningful language. Ask someone what ‘Tucson’ means and you might well get a puzzled look followed by (something like) “It doesn’t really ‘mean’ anything, it’s the name of a city in Arizona!” In contrast, you might well get a response to a question about the meaning of ‘city.’ It means (you might be told) something like ‘metropolitan area.’

The central objections to Millianism concern special cases that the theory seems unable to accommodate: cases involving identity sentences, propositional attitude attributions, and ‘empty’ names (names without bearers). These are the very same cases that provide the central motivation for description theories.

Description Theories

Description theories (associated with Frege, Russell, and, more recently, Searle) claim that the meaning of a proper name is the descriptive or (more generally) conceptual content with which it is associated. For Frege (1892/1962), this associated content (which he called ‘sense’) is the ‘mode of presentation’ of the object referred to by the name. It represents the speaker’s ‘take’ or perspective on the name’s referent. For others (e.g., Russell, 1912/1917) the associated content is said to be a matter of what the speaker ‘has in

mind' when using a name. Description theorists sometimes talk as though associated content can be captured via a single description, one shared by members of the linguistic community at large (Russell, 1905, 1919). Yet both Frege (1892/1962) and Russell (1912/1917) acknowledged that the associated content could vary from speaker to speaker. For Russell (1912/1917), and perhaps for Frege as well, such content could even vary for an individual speaker over time. According to contemporary descriptivist Searle (1958, 1983), to the extent that the sense of a proper name can be captured linguistically, it is captured by a 'cluster' of descriptions the individual speaker associates with the name.

The virtues of description theories have been much touted in the philosophical literature. Specifically, such accounts appear to solve a variety of puzzles that can be illustrated by the following sentences:

- (1) Hesperus is Phosphorus.
- (2) Alice believes that Samuel Langhorne Clemens has a funny middle name.
- (3) Sherlock Holmes lives on Baker Street.
- (4) Santa Claus does not exist.

Sentences such as (1) are known as 'identity sentences,' sentences such as (2) are known as 'propositional attitude attributions' (because they attribute an attitude, such as belief or doubt, to an agent). Sentences (3) and (4) contain 'empty' names, and the latter is known as a 'negative existential' because it denies the existence of something.

Sentences such as these are puzzling on the assumption that Millianism is true. Suppose the meaning of a proper name is simply its bearer. Then (1), if true, is trivially true, and (2) is synonymous with (5):

- (5) Alice believes that Mark Twain has a funny middle name.

Whereas (3) is meaningless (due to a subject term without a bearer), (4) is nearly contradictory: If the subject term is meaningful (if it has a bearer), the sentence is false. Intuitively, however, all of this is mistaken. (1) is both true and informative, and (2) and (5) are not synonymous because the former might be true while the latter is false. (3) is meaningful and (4) is not only meaningful but also true. How can this be? Suppose we construe the meaning of a proper name as the descriptive content with which it is associated. Then proper names are, in effect, descriptions. Consistent with this general picture, let us adopt the following stipulations: 'Hesperus' means 'the brightest star in the evening sky,' 'Phosphorus' means 'the brightest star in the morning sky,' 'Samuel Langhorne Clemens' means 'my eccentric neighbor

Sam,' 'Sherlock Holmes' means 'the famous London detective featured in the Conan Doyle stories,' and 'Santa Claus' means 'the jolly bearer of Christmas gifts who lives at the North Pole.' Given these assumptions, we can explain the informativeness of (1), the fact that (2) and (5) mean different things, the meaningfulness of (3), and the truth of (4). To see this, one need only substitute for the proper name the description that captures the name's associated content (e.g., 'The brightest star in the evening sky is the brightest star in the morning sky'). The resultant sentences arguably have the same meaning properties as the original sentences – a fact that lends credence to descriptive accounts of proper names. (For details, see Frege (1892/1962) and Russell (1905), the latter of which contains Russell's analysis of the sorts of sentences that result when a proper name is replaced with a definite description.)

Contemporary Millians (including Salmon, 1986) are not impressed by the description theorist's analysis of sentences such as (1)–(5) and have responded that their own theories can easily account for the intuitive data. The basic idea is to claim that the intuitions surrounding such sentences are the result of mistaking what a speaker might communicate by their utterance with what the sentences themselves literally express (which is just as Millianism claims). Moreover, description theories of meaning are not problem-free. For instance, if a name 'N' means what some description 'the *F*' means, then why doesn't '*N* is the *F*' (e.g., 'Cheney is the current U.S. vice president') sound as trivial (in 2004) as 'bachelors are unmarried'? (For this and other problems, see Devitt and Sterelny, 1999.)

Theories of Reference

Some philosophers have thought that description theories of meaning can be extended to account for reference. These philosophers advocate description theories of reference, the *locus classicus* of which is Frege's (1892/1962) 'On sense and reference.' Such theories are no longer as popular as they once were. Since the 1970's, causal theories of reference have provided an attractive alternative to description theories. The causal theory (as originally sketched by Kripke in a series of lectures later published as *Naming and necessity* (Kripke, 1980)) arose in large part out of dissatisfaction with description theories. Let us therefore begin with description theories of reference.

Description Theories

According to any such theory, the referent of a proper name is determined by the descriptive content with

which it is associated; in other words, the referent is whatever 'satisfies' the associated content. According to some philosophers (Russell, 1905, 1919), the descriptive content can generally be captured linguistically; others (Searle, 1983) disagree. (Here, differences between versions of description theories of meaning are mirrored.)

The motivation for description theories is both intuitive and methodological. Ask a speaker to what he or she is referring when he or she uses a particular name and the speaker will likely provide a description in response. Ask me to what I am referring when I talk of 'Mount Everest' and I might well respond with an appropriate description, such as 'the tallest mountain in the world.' Such intuitive considerations at least suggest that a proper name (as used by a speaker) refers to its bearer in virtue of that entity's satisfying some descriptive criterion associated with the name. The theory also has a clear methodological virtue when coupled with a description theory of meaning. In this way, a single phenomenon (associated conceptual content) explains both meaning and reference.

The central objections to the theory include the following two, both from Kripke (1980). First, a name can refer uniquely to its bearer even if the associated descriptive content is satisfied by more than one object/individual. 'Cicero' refers uniquely to the famous Roman orator also known as 'Tully' even if the associated descriptive content is simply 'a Roman orator.' This suggests that something more than (or other than) associated descriptive content is needed to determine reference. Second, a name can refer to its bearer even if the associated descriptive content is uniquely satisfied by some other object/individual. 'Einstein' refers to the famous German physicist even if the associated descriptive content (e.g., 'the inventor of the atomic bomb') describes someone else (Oppenheimer). This suggests that something other than descriptive content determines reference. (For further objections to the description theory, see Devitt and Sterelny, 1999.)

Many philosophers (but not all, including Searle, 1983) have viewed Kripke's objections to description theories of reference as decisive. As a result, other theories have been developed, including, most notably, causal theories of reference, the first of which was sketched in Kripke's (1980) *Naming and necessity*.

Causal Theories

A causal theory of reference claims that the link between a name and its bearer is (at least generally) causal in nature. Following Devitt and Sterelny (1999), one can think of such theories as (ideally) having two components: a theory of reference 'fixing'

and a theory of reference 'borrowing.' The former explains how a name first gets attached to a certain entity; the latter explains how members of the linguistic community at large are subsequently able to use the name to refer to that entity. So construed, causal theories are easily illustrated. My daughter has a Chihuahua named 'Cocoa.' When she first brought him home, she decided to call him 'Cocoa' because of his chocolate color. She proceeded to call him 'Cocoa,' and Cocoa he thereby became. Reference was accordingly 'fixed' and all those present at the initial applications of the name thereby acquired the ability to use the name. The ability was acquired in virtue of having perceived (and thus been causally affected by) these initial applications. My daughter subsequently told her friends about her Chihuahua (using his name to do so) and thereby enabled those same friends to refer to him via 'Cocoa.' In this way, the causal (perceptual) chain of communication, originating in the initial applications of the name, is extended. My daughter's friends can extend the chain further, enabling still others to refer to Cocoa via 'Cocoa,' simply by using his name in their (attentive) presence. Reference is thereby 'borrowed.'

Although reference is generally causal on this picture, exceptions are acknowledged. It is uncontroversial that there are proper names whose reference is fixed by description. As Kripke (1980) noted, when 'Neptune' was introduced into the language by the astronomer Leverrier, its reference was stipulated to be 'the planetary cause of Uranus's orbital perturbations.' (See Evans, 1979, for a discussion of such 'descriptive' names.)

A central virtue of causal theories is that they avoid the problems of description theories. They claim, in effect, that associated descriptive content is irrelevant to reference. A second (no less important) virtue is that such theories provide a simple and intuitive answer to the question, 'How does language attach to reality?' In a word: causality. (See Devitt and Sterelny, 1999, for details.)

Nevertheless, causal theories are not without their problems. Gareth Evans, in his classic paper 'The causal theory of names' (1973), presented a telling objection to the theory, as originally sketched by Kripke. According to Evans, the causal theory fails to account for the fact of reference change. As Evans pointed out, 'Madagascar' once referred to a portion of the African mainland, but now it refers to the island. Evans argued that the causal theory cannot explain how such changes could occur. (But see Devitt and Sterelny, 1999, for a compelling rejoinder.) In developing an alternative that accounts for reference change, Evans was led to a hybrid theory, one that combines elements from both descriptive and causal theories.

Hybrid Theories

According to Evans's hybrid theory, a name refers to the dominant causal origin of the descriptive information with which it is associated. The intuitive pull of the theory is easily illustrated. Suppose a tattered and centuries-old manuscript is discovered. On its cover is emblazoned the name 'Melford Bibbins.' The manuscript is widely discussed among academics, and its author, known to all as 'Melford Bibbins,' becomes famous for his controversial philosophical views. Intuitively, the individual being referred to is the author of the manuscript, even if it turns out that 'Melford Bibbins' was the name of the scribe to whom the author dictated his work. Evans's theory gets it right: the author of the manuscript is the causal origin of the descriptive information associated with the name and thus the name's referent. The scribe is not the referent, although he is (by hypothesis) the individual at the origin of a causal chain that began with the introduction of the name 'Melford Bibbins' into the language. It would be a mistake to suppose that reference can be explained here via associated descriptive content. Suppose that such content (*the proponent of such-and-such crazy philosophical views*) misconstrues the author's actual views but coincidentally describes precisely the views of some unknown hermit living somewhere in the Appalachian Mountains. In such a case, the author of the manuscript (the intuitive referent of the name) does not satisfy the associated content. Nevertheless, he is arguably the causal origin of that content insofar as he produced the work that generated it.

Devitt and Sterelny (1999) also advocated a hybrid theory. They claimed that reference fixing, to be successful, must involve a conceptual element. If you see a rock but think it is a tortoise and attempt to dub it 'Slow Poke,' reference fixing fails. They called this the 'qua-problem' and solved it by supposing that in order to fix the reference of a name, the speaker must have an accurate (if general) concept of the intended bearer.

Other Expressions

Philosophers often appeal to other expressions in developing their theories of proper names. They do so for (at least) two reasons: to clarify their theories and to provide methodological motivation for those theories. When a contrast is observed, clarification is generally the motivation. When a similarity is noted, promotion of the theory's generality is often the motivation.

Definite Descriptions

Definite descriptions are expressions of the form 'the F ,' such as 'the current vice president of the United

States.' How do these expressions compare with proper names? Millians generally argue they are importantly different: descriptions refer via satisfaction (or 'denotation'). Names refer directly, not in virtue of associated descriptive content. (For this reason, Millian theories are sometimes referred to as 'direct reference' theories.) Russell, in contrast, argued that proper names are 'disguised' definite descriptions and thus subject to the quantificational rendering provided by his theory of descriptions (1905). Frege (1892/1962) similarly treated definite descriptions as semantically of a piece with proper names, claiming that both sorts of expressions have their reference determined by their associated conceptual content (or 'sense').

Natural Kind Terms

Natural kind terms are terms that refer to kinds of things found in nature – 'water,' 'tiger,' and 'lemon' being stock examples. How do these expressions compare with proper names? Kripke (1980) suggested that these expressions are much like proper names: their reference is not determined by any associated conceptual content but by causal chains of the sort that link proper names to their bearers. These same ideas were developed by Putnam (1975) and later and in greater detail by Devitt and Sterelny (1999).

Propositional Attitude Ascription: Philosophical Aspects

L Clapp, Illinois Wesleyan University, Bloomington, IL, USA

Paradigmatic **propositional attitude ascriptions** (in English) are sentences of the form **A Vs that S**, where **A** is a singular definite noun phrase referring to a rational agent, **S** is a sentence, and **V** is a propositional attitude verb. Paradigmatic propositional attitude verbs include 'believe', 'doubt', 'realize', 'hope', 'regret', etc. Such verbs refer to **intentional mental states** with **representational content**, where this content can be evaluated for truth or falsity, and thus can be identified with a **proposition**. (What are sometimes called *verbs of saying*, e.g., 'say', 'deny', 'announce', are closely related to, but typically distinguished from, propositional attitude verbs.) Because propositional attitude verbs refer to intentional states with propositional content, it is natural to endorse a **relational analysis** of propositional attitude ascriptions: an assertion of 'John hopes that Mary won' says that the referent of 'John' bears the mental relation (or *attitude* in Russell's 1940 terminology) referred to by 'hopes' toward the proposition expressed by the complement clause 'that Mary won.' Similarly, an assertion of 'John doubts that Tom is happy' says that John bears a different relation, viz. doubting, toward a different proposition, viz. that Tom is happy.

Analytic philosophers have been, and continue to be, concerned to formulate an adequate semantic analysis of propositional attitude ascriptions for several reasons. One reason stems from philosophers' desire to understand the nature of mental states. What is, e.g., a belief? Is the existence of beliefs compatible with **physicalism**? If not, then should we be **eliminativists** about mental states, and deny that they really exist, or should we reject physicalism in favor of some sort of **dualism**? How can a mental state **represent** things as being a certain way? i.e., what is it for one entity to be **about** another? Does having a belief

require one to instantiate some sort of internal representational state (as **cognitivists** claim), or is it merely a matter of being disposed to behave in various ways (as **behaviorists** claim)? Whatever view one adopts toward these broader philosophical issues concerning the nature of mental states must be compatible with an adequate semantic analysis of how we talk about such states.

Another reason, perhaps the principle reason, philosophers are concerned with propositional attitude ascriptions stems from the close relationship between natural language and thought, and the apparent **compositionality** exhibited by both. What we can think is what is expressed by utterances of declarative sentences; if what we think are **thoughts**, and if what is expressed by utterances of declarative sentences are propositions, then what we think are propositions. Moreover, philosophers have argued that in order to explain the **productivity**, **interpretability**, and **systematicity** of language, and thus thought, some sort of **principle of semantic compositionality** must hold for language, and thus thought (see Frege (1914) and Davidson (1965) for appeals to productivity and interpretability. See Evans (1982) and Fodor (1998) for appeals to systematicity. Frege also appealed to compositionality to explain the **unity of the proposition**. See Frege (1891 and 1892b). Consequently, many analytic philosophers have endorsed some version of the following **principle of semantic compositionality**:

The proposition expressed by a sentence **S** in a context **c** is a function of (i) the **logical form** of **S**, and (ii) the **semantic values** invoked by **S** in **c**.

(The relativization to context is necessary to account for sentences containing **context sensitive** words.) The reason that philosophers interested in language and thought have been especially concerned with propositional attitude ascriptions is that these sentences provide apparent counterexamples against this otherwise well-motivated principle; this is known as the **opacity** problem for attitude ascriptions. The focus of my

remarks here will be on the opacity problem and influential proposals for its solution.

Consider the classic case of the hapless ancient astronomer: He used 'Hesperus' to refer to the first heavenly body to appear at dusk, and 'Phosphorus' to refer to the last heavenly body to disappear at dawn. But he did not realize that these names are coreferential; they both refer to Venus. Now consider the following attitude ascriptions:

- (1) The astronomer believed that Hesperus was visible at dusk.
- (2) The astronomer believed that Phosphorus was visible at dusk.

Given the astronomer's ignorance of the identity of Hesperus and Phosphorus, (1) is true and (2) is false. But that (1) and (2) differ in truth value is at least an apparent counterexample to the compositionality principle: If it is granted that (1) and (2) have the same logical form, and that the semantic value contributed by a word is its referent, then, given that 'Hesperus' and 'Phosphorus' are coreferential, semantic compositionality seems to require that (1) and (2) express the same proposition, and thus cannot differ in truth value. The opacity problem is sometimes called *substitution failure*: in (1) 'Phosphorus' cannot be substituted *salva veritate* for 'Hesperus.' Linguistic environments in which coreferential terms cannot be substituted *salva veritate* are known as **opaque**, as opposed to **transparent**, contexts.

Responses to the opacity problem can be divided into **conservative** proposals and **radical** proposals. Conservative proposals attempt to preserve the principle of semantic compositionality by somehow explaining away the apparent counterexamples. Conservative proposals can be subdivided into **semantic** conservative proposals, which appeal to the **meanings** of expressions to explain away the apparent counterexamples, and **pragmatic** conservative proposals, which appeal to how expressions are **used**. In contrast to conservative proposals, **radical proposals** accept the apparent counterexamples provided by attitude ascriptions, and thus reject the principle of semantic compositionality and offer alternative conceptions of semantics in its place.

To propose a **semantic conservative solution** to the opacity problem, then, is to provide an account of semantic values, and how they are invoked and combined, which preserves the above principle of compositionality yet explains why, e.g., (1) and (2) express different propositions. If the datum that (1) and (2) express different propositions is granted, and it is granted that (1) and (2) have the same logical form, then the general strategy one must adopt is clear: one must argue that (1) and (2) somehow invoke

additional, extrareferential, semantic values. Semantic conservative proposals all have this general strategy in common; where they differ is over **what** they take the requisite additional semantic values to be, and over **how** attitude ascriptions invoke different such additional semantic values.

The first, and probably most influential, semantic conservative proposal was presented by Frege (1892a). Indeed, Frege was the first to clearly formulate the opacity problem, and most subsequent work on the problem is a development of, or response to, Frege's seminal paper. A key feature of Frege's proposal is the thesis that words embedded in the complement clauses of attitude ascriptions **shift referents**; when words occur embedded in such **opaque** contexts, their semantic values are not their 'ordinary referents,' but are instead more finely individuated entities, which Frege called 'indirect referents.' Frege posited abstract objects he called **senses** to serve as indirect referents. A sense of a word is alleged to be a 'mode of presentation' of the referent of the word (if the word has a referent). To return to the hapless astronomer, Frege would say that the referent, Venus, is presented to the astronomer in two different ways; one of these ways is the sense of 'Hesperus,' and the other is the sense of 'Phosphorus.' The astronomer fails to recognize that Hesperus is Phosphorus because he fails to realize that these different modes of presentation are in fact modes of presentation of, or ways of thinking about, the same referent. If it is granted that 'Hesperus' and 'Phosphorus,' though coreferential, nonetheless express different senses, then, because of referent shifting, (1) and (2) invoke different semantic values. And consequently, that these sentences express different propositions, and have different truth values, is no threat to semantic compositionality.

Many theorists endorse Frege's thesis that words embedded in the complement clauses of attitude ascriptions shift referents, yet, influenced by broader philosophical commitments, they reject senses, the abstract objects Frege posited to serve as indirect referents. Other sorts of entities posited to serve as indirect referents include **intensions** (Montague, 1974), sentences (Carnap, 1946), and **mental representations** (Fodor, 1978). All theories which allow for referent shifting, however, face a common difficulty: As Quine (1956) noted, attitude ascriptions are ambiguous (or at least context sensitive). For some utterances of attitude ascriptions, what is relevant for determining truth conditions is simply the referent of an embedded word, rather than the word, or some other sort of indirect referent. And for these so-called *de re* utterances of attitude ascriptions, Frege's referent shifting thesis is inappropriate. But, as Frege

noted, for other, so-called *de dicto*, utterances of attitude ascriptions, it seems that something other than the referents of embedded words is relevant for determining truth conditions. It is now widely accepted that in different contexts the same attitude ascription (sentence type) can express different truth conditions; in particular, some utterances of, e.g., the type of (1) are *de re* (or **transparent**), while other utterances like (1) are *de dicto* (or **opaque**).

The recognition of the context sensitivity of attitude ascriptions has led philosophers to add complexities to the semantic conservative strategy. Quine (1956) proposes that, if propositional attitudes are to be countenanced at all, propositional attitude verbs ought to be treated as ambiguous between a **relational** (*de re*) sense, and a **notional** (*de dicto*) sense. More recent proposals build on Carnap's (1946) theory, and identify indirect referents not with words, but with abstract structures composed of both words and their ordinary referents (relative to a context) combined. These Carnap-inspired theories attempt to account for the context sensitivity of attitude ascriptions by allowing what is necessary for an agent to hold the relevant mental relation to the combined entity to vary across contexts (see Richard, 1990 and Higginbotham, 1991).

Thus far, I have reviewed semantic conservative proposals that follow Frege in maintaining that words in complement clauses of attitude ascriptions shift their referents; where the proposals discussed thus far have differed from each other concerns **what** the additional semantic values are. Other semantic conservative proposals, however, disagree with Frege not only concerning **what** the requisite additional semantic values are, but they also reject Frege's referent shifting thesis. An early alternative to Frege's indirect reference strategy was proposed by Russell (1919). Russell's proposal preserves the simple idea that semantic values are **always only** ordinary referents, but he achieves this result at the cost of allowing the **logical form** of a sentence to differ significantly from its **surface form**. According to Russell, what appear to be referring terms, e.g., 'Hesperus' and 'Phosphorus,' are merely abbreviations for "denoting phrases" composed of quantifiers and unpronounced genuine referring terms; Russell called these posited unpronounced genuine referring terms "logically proper names." According to Russell then, despite appearances, Venus is not the referent of any genuine referring term in the logical form of either (1) or (2). Rather, the apparent names 'Hesperus' and 'Phosphorus' abbreviate denoting phrases comprised of different, noncoreferential, logically proper names. Thus, that (1) and (2) express different propositions is not a counterexample to semantic compositionality,

because, according to Russell, the sentences invoke different semantic values. (Not surprisingly, Russell never presents a full reduction of an apparent name into a denoting phrase comprised of logically proper names.)

A more recent proposal similar in spirit to Russell's is the "hidden indexical" analysis (see Schiffer, 1977 and Crimmins, 1992). This proposal maintains that the additional semantic values required for distinguishing the propositions expressed by utterances of (1) and (2) are the referents of 'hidden' – phonologically unrealized – indexical items that are somehow present in the logical form, but not in the surface form, of the sentence. Crimmins takes the posited hidden indexicals to refer (in contexts) to "mental particulars," token mental representations that, similar to Frege's senses, are ways of thinking of ordinary referents. The hidden indexical analysis thus does not deny that, e.g., Venus is a semantic value invoked by both utterances (1) and (2), because Venus is the referent of both 'Hesperus' and 'Phosphorus.' But that such utterances express different propositions is nonetheless not a counterexample to semantic compositionality because the presence of hidden indexicals allows the utterances to invoke different mental particulars as 'unarticulated' semantic values.

Another influential semantic conservative proposal that rejects referent shifting is Davidson's (1968) "paratactic" analysis of indirect speech. Davidson proposes that an indirect speech report with the surface form 'A said that S' has the logical form of **two** sentences: first, 'A said **that**,' and second, 'S.' The word 'that' in the first sentence is interpreted as a **demonstrative**, and in an utterance with the surface form 'A said that S,' the demonstrative refers to the subsequent **utterance** of 'S.' Thus, in Davidson's proposal, the additional semantic value invoked by an utterance of an indirect speech report is the very act of uttering the sentence embedded in the complement clause. According to Davidson's proposal, an utterance with the surface form 'A said that S' is true just in the case the agent referred to by 'A' performed an utterance that is relevantly similar to the referent of 'that,' where this referent is the **utterance** of the embedded 'S.' Davidson applied his analysis only to indirect speech reports, but others, such as Lepore and Loewer (1989), have extended Davidson's analysis so that it applies to attitude ascriptions.

Whereas semantic conservative proposals accept that, e.g., (1) and (2) express different propositions and attempt to reconcile this datum with the principle of semantic compositionality, **pragmatic conservative proposals** reject the datum and thereby undermine the apparent counterexample to semantic compositionality. According to pragmatic conservative

proposals, (1) and (2) do not present a counterexample to compositionality because, despite our pre-theoretic judgments to the contrary, they do not express different propositions, and they do not differ in truth value. Support for this seemingly implausible strategy comes from two principle sources: First, there are influential arguments due to Kripke (1972) and Kaplan (1977) in support of the **thesis of direct reference**, according to which the only semantically relevant feature ever associated with some terms – names, demonstratives, and indexicals being the paradigmatic cases – is the referent of the term. The thesis of direct reference thus entails that, e.g., utterances (1) and (2) express the same proposition. Second, there is Grice's (1975) distinction between **what is said** by an utterance and **what is merely implied** by an utterance. According to Grice, **what is said** is the domain of **semantics** and thus must conform to the compositionality principle, while **what is implied** is the domain of **pragmatics**, and thus need not conform to the principle. According to the pragmatic conservative strategy then, utterances (1) and (2) semantically say the same thing, but they pragmatically imply different things. And our pre-theoretic judgment that utterances (1) and (2) say different things is a result of our naively conflating **semantically expressed** information with **pragmatically implied** information. Pragmatic conservative proposals are developed by Salmon (1986) and Soames (2002).

In contrast to **conservative proposals** which attempt to preserve semantic compositionality by somehow explaining away the at least apparent counterexamples posed by attitude ascriptions, **radical proposals** accept the counterexamples and reject semantic compositionality. Given the fundamental role that the principle of compositionality has played in semantics and analytic philosophy generally, a theorist who endorses a radical proposal must provide an alternative conception of what it is to provide a semantic analysis. Moreover, this alternative conception must be at least compatible with the phenomena of **productivity**, **interpretability**, and **systematicity**. One sort of radical proposal falls within the broader movement known as **Radical Pragmatics**. Radical Pragmatics is characterized by the thesis that the linguistic meaning associated with an utterance underdetermines what is said by the utterance; i.e., knowing the logical form of an utterance and knowing the referents of all the words (or other relevant features) does not suffice for determining what is said by the utterance; in order to arrive at something truth-evaluable, additional processing is required. **Relevance Theory**, as proposed by Sperber and Wilson (1986), is a paradigmatic example of Radical Pragmatics. Thus, from the perspective of Radical Pragmatics, it is not

particularly problematic that utterances (1) and (2) express distinct truth conditions. A version of Radical Pragmatics is applied to attitude ascriptions in Bach (1997).

Another sort of radical proposal falls within the broader movement known as **Dynamic Semantics**. According to Dynamic Semantics, the semantic content of a declarative utterance is not a truth-evaluable proposition, but rather linguistically encoded general instructions (i.e., a 'context change potential') for updating the set of beliefs shared between the speaker and his audience (i.e., the 'common ground'). To determine **what is said** by an utterance, one must apply the linguistically encoded general instructions to the set of shared beliefs. Thus, **what is said** depends not only upon the logical form of the uttered sentence and the semantic values of the words in it, but also upon what the shared beliefs of the speaker and his audience happen to be. A paradigmatic example of Dynamic Semantics is **Discourse Representation Theory**, as proposed by Kamp and Ryle (1993). Because utterances (1) and (2) encode different instructions for updating sets of shared beliefs, **what is said** by such utterances (relative to the same set of shared beliefs) can differ. Thus, from the perspective of Dynamic Semantics also, it is not particularly problematic that such utterances are interpreted as expressing distinct truth conditions. This sort of dynamic approach is applied to the phenomenon of opacity in Asher (1993).

Propositions

S Crawford, Lancaster University, Lancaster, UK

When an English speaker utters the sentence 'Snow is white' and a French speaker utters the sentence 'La neige est blanche,' there is a clear sense in which they have both said the same thing. Moreover, given that they both intend sincerely to express their beliefs by uttering these sentences, there seems a clear sense in which they both believe the same thing. Philosophers call this thing that both have said and that both believe a *proposition*. The declarative sentences we utter and write down are said to have propositions as their linguistic meanings and to express those propositions. Two or more sentences (in the same language or in different ones) can have the same proposition as their meaning – that is, they can express the same proposition – just as different numerals (e.g., the Arabic numeral '4' and the Roman numeral 'IV') can designate the same number, namely four. Moreover, propositions are supposed to be the contents of many of our mental states, such as belief, knowledge, doubt, supposition, memory, desire, intention, and so on. Russell (1903) called these mental states "propositional attitudes."

Roles Played by Propositions

The notion of a proposition has played, and continues to play, important roles in the philosophy of logic, philosophy of language, and philosophy of mind. Three of those roles have been mentioned already: Propositions are the linguistic meanings of the sentences we utter or write down, they are the contents of our sayings when we utter or write down those sentences, and they are the contents of our thoughts. Propositions are commonly thought to have other important functions as well. They are often taken to be the "primary bearers" of truth and falsity, in the sense that the sentences we utter and the beliefs we have are true or false only derivatively in virtue of the propositions associated with them being true or false. Propositions are also said to be the primary bearers of modal properties, such as necessity, contingency, possibility, impossibility, and so on. And logical relations, such as consistency, inconsistency, and entailment, are said to hold between or among propositions.

It is a good question whether any single notion of a proposition can play all these roles at once. Sentences containing indexicals, for example, cause difficulties in this regard, for they seem to suggest that the linguistic meaning of a sentence may differ from the

proposition it expresses. When I say ‘I’m hungry,’ and when you say ‘I’m hungry,’ there is a sense in which our respective sentences have the same meaning; but it also seems clear that they express different propositions, one about me and the other about you. Conversely, when I say ‘I’m hungry’ and you say, addressing me, ‘You’re hungry,’ we seem to have said the same thing – that is, expressed the same proposition, a proposition about me – but uttered sentences with different meanings. In light of this, Kaplan (1989) has distinguished between the *character* (roughly, linguistic meaning) and the *content* (proposition expressed) of a sentence. Whether any single notion of a proposition can play all these different roles depends very much on what propositions are taken to be. So what then are propositions exactly? What are these entities, propositions, that we assert and believe and that are true or false and necessary or contingent?

Propositions as Abstract Entities

The history and development of the concept of the proposition are a long and complex story (Gale, 1967); but contemporary accounts derive most immediately from Frege’s attack on psychologism and the *fin de siècle* revolt against idealism inaugurated by Russell and Moore (Frege, 1892a, 1918; Moore, 1899; Russell, 1903; Hylton, 1984). The core of this shared account is the idea that propositions are mind-independent, extralinguistic abstract entities akin to numbers, mathematical functions, and sets.

This core idea subsequently came under persistent attack by Quine (1960, 1986) who viewed propositions (and other ‘intensional’ entities such as properties and relations) as ‘creatures of darkness’ owing to the alleged lack of any criteria for individuating them, as well as their essential involvement with what Quine (1951) deemed the obscure and suspect notions of meaning and synonymy. In the service of his sparse desert ontology, Quine proposed to replace abstract propositions with concrete sentences (propositions are really just unnecessary ‘shadows’ of sentences anyway, to invoke Wittgenstein’s metaphor) or, more accurately, with mathematical sequences of word-tokens that have been uttered or inscribed at some time (Quine, 1960). However, neither Quine’s relentless critique of propositions as abstract entities nor his replacement of them with sentences has been widely accepted. Moreover, despite Quine’s closely related attack on modal notions, such as necessity and possibility, the rise of modal logic and modal metaphysics continued unabated and accorded a

central place to propositions construed as abstract entities. The seminal work of Kripke (1972) was instrumental in turning the tide against Quine.

Let us then turn to the most popular contemporary approaches to the nature of propositions as mind-independent, extralinguistic abstract entities. As we shall see, there has been some lack of clarity about whether theories of propositions are theories about what propositions *are*, ontologically speaking, or whether theories of propositions are theories about how they should best be represented or modeled in a formal semantic theory.

Two Approaches: Structured and Structureless Entities

Generally speaking, theories of propositions can be divided into two sorts. The first takes propositions to be certain kinds of structured entities with components standing in various relations to each other, with the structure of the entities roughly mirroring the structure of the sentences that express them. The second takes propositions to be structureless entities. The structureless approach invokes the notion of a “possible world,” borrowed from the new model theory for modal logic developed in the 1950s and 1960s, known as “possible worlds semantics.” A possible world is a “way things could have been.” The idea is that a proposition is a set of possible worlds (the set of worlds at which the proposition is true), or equivalently, a proposition is a function (in the mathematical sense) from the set of possible worlds to the set of true values.

That the possible-worlds approach to propositions treats propositions as structureless is easily seen. Consider the sentences ‘Russell is not alive and Frege is not alive’ and ‘It is not true that either Russell is alive or Frege is alive.’ These sentences have very different structures: the first is a conjunction of two negations, and the second is a negation of a disjunction. Yet, they are true in the same possible worlds because they are logically equivalent. According to the possible-worlds approach, both sentences therefore express the same proposition.

According to the structured approach, however, these two sentences express different propositions because in the structured approach a proposition is not individuated in terms of the possible worlds in which it is true, but rather in terms of the constituents that make up the proposition. On this account, a proposition is a structured entity composed of parts, where the parts and the order of composition more or less mirror the parts and order of composition of the sentences that express the proposition.

Two Structured Approaches: Russellian and Fregean

There are, broadly speaking, two types of structured theory, the first deriving from Russell (1903) and the second from Frege (1892a), which are distinguished from each other by what they take the constituents of propositions to be. According to the Russellian (or “neo-Russellian”) approach, the constituents of the propositions we assert and believe, and to which truth and falsity and modal properties belong, are the objects, properties, and relations that our assertions and beliefs are about: desks, trees, other people, and other everyday objects. According to the Fregean approach, propositional constituents are rather ‘senses’ or ‘modes of presentation’ (or concepts or ‘ways of thinking’) of the objects, properties, and relations that our saying and thoughts are about: modes of presentation of desks, trees, and other people. There are also combination views, according to which propositional constituents are both the things our sayings and thoughts are about and modes of presentation of those things.

On the Russellian view, propositions are identified with ordered pairs of n objects and an n -place relation: $\langle \langle x_1, \dots, x_n \rangle, X^n \rangle$. The proposition that Maggie is cooking is thus identical with the ordered pair: $\langle \text{Maggie}, \text{cooking} \rangle$. The Fregean view identifies propositions with ordered pairs of n modes of presentation (of objects) and an n -place mode of presentation (of a relation): $\langle \langle m_1, \dots, m_n \rangle, M^n \rangle$. Here, m_1, \dots, m_n are modes of presentation of x_1, \dots, x_n , and M^n is a mode of presentation of X^n . The proposition that Maggie is cooking, for the Fregean, is thus the ordered pair: $\langle \text{mode of presentation of Maggie}, \text{mode of presentation of cooking} \rangle$.

A third view, which combines Russellian and Fregean elements, has it that the propositions we believe contain both the items our beliefs are about and modes of presentation. For example, we might believe or assert ‘quasisingular propositions’ (Schiffer, 1978; Recanati, 1993) that contain objects, properties, and relations, as well as modes of presentation of all these things: $\langle \langle \langle x_1, m_1 \rangle \dots \langle x_n, m_n \rangle \rangle, \langle X^n, M^n \rangle \rangle$. According to this view, when Tom believes Maggie is cooking, the proposition he believes is identical with the ordered pair: $\langle \langle \text{Maggie}, \text{mode of presentation of Maggie} \rangle, \langle \text{cooking}, \text{mode of presentation of cooking} \rangle \rangle$. It is possible, of course, to hold that sometimes we believe one type of proposition (e.g., a Russellian one) and sometimes we believe another type (e.g., a quasisingular one), depending on the situation and context in question. For present purposes, however, the important point is that propositional constituents are either objects, properties, and

relations or modes of presentation of these things (often just called *concepts* of them – though this contemporary use of the term ‘concept’ should be distinguished from Frege’s very different use of that term). And the propositions we believe – if there are such things – are composed out of such items in some way or another.

Ontology or Semantics?

So far, we have been speaking as if both the structureless and structured accounts of propositions were accounts of what propositions are. If this is correct, then, on the structureless account, what we assert when we assert a proposition and what we believe when we believe a proposition is a set or a function. Similarly, according to the structured accounts, to assert or to believe that Maggie is cooking is to stand in a relation to an ordered set. On the face of it, this does indeed seem very implausible (Bealer, 1998). Moreover, it is hard to understand how ordered sets could be true or false or necessary or contingent. These set-theoretic constructions just do not seem to be the kinds of things that can have the properties that propositions are supposed to have.

The structured position suffers from another problem too: *which* ordered set is the proposition that Maggie is cooking? Taking the Russellian approach as an illustration, is it $\langle \text{Maggie}, \text{cooking} \rangle$ or is it $\langle \text{cooking}, \text{Maggie} \rangle$? There seems no way to determine (nonarbitrarily) which ordered set a certain proposition is (Bealer, 1998; Jubien, 2001). This general difficulty of reducing abstract objects, such as numbers, to sets is due to Benacerraff (1965).

In light of this, it seems best to take the structureless and structured approaches as rival ways of representing propositions in a formal semantic theory and not as accounts of what propositions are. Whether or not this is an adequate response to the foregoing objections, it is evident that, even interpreted as proposals about how to represent propositions, each approach is still not without its problems.

A Problem for the Structureless Approach

The structureless account appears to face what seems to be a devastating objection, stemming from the fact that it implies that all necessarily equivalent propositions are identical. Since the sentences ‘A sister is a female sibling’ and ‘A brother is a male sibling’ are true in all possible worlds, they express the same proposition. But, these sentences obviously have different meanings and thus seem to express different propositions. Moreover, if belief is a binary relation between a subject and a proposition, and a

proposition is a set of possible worlds, then, for any necessarily equivalent propositions *P* and *Q*, if *S* believes *P*, then it follows that *S* believes *Q*. So, for example, if Maggie believes that $5 + 5 = 10$, she must then believe that arithmetic is incomplete, since both these things are true in every possible world. Valiant efforts have been made to mitigate these counter-intuitive consequences (Stalnaker, 1984), but none has achieved widespread acceptance.

The very structurelessness of propositions on the possible worlds account means that propositions are not “fine grained” enough to serve as the objects of attitudes and the meanings of sentences. There are just not enough to go around on the possible worlds account. (Another approach to this problem, within the possible worlds framework, found in the work of Lewis (1972) and Montague (1974), invokes “structured intensions” and derived from Carnap’s (1956) notion of “intensional isomorphism types.”)

Problems for the Structured Approaches

The majority of philosophers, then, adopt a structured approach, either a Russellian one or a Fregean one. Turning first to the Russellian representation of propositions, it is evident that it is able to distinguish among necessarily equivalent propositions. The propositions expressed by the sentences ‘Sisters are female siblings’ and ‘Brothers are male siblings’ have different constituents and are therefore distinct. So the Russellian manages to achieve a certain fineness of grain in its representation of propositions. It is a matter of controversy, however, whether his representation of propositions is fine enough. For the Russellian, the sentences ‘George Eliot is a novelist’ and ‘Mary Anne Evans is a novelist’ express the same proposition, because the parts of each sentence (e.g., the proper names and predicates) refer to (and are true of) the same things, and it is these same things that form the constituents of the propositions that each expresses. Now, whether or not we want to say that these sentences have different meanings, it has seemed to some philosophers that we do want to say that someone could believe George Eliot is a novelist without also believing that Mary Ann Evans is a novelist (even though George Eliot is Mary Ann Evans). In other words, belief content – and cognitive content more generally – seems to be extremely fine-grained. Importantly, cognitive content seems to be more fine-grained than a representation – using only the worldly objects, properties, and relations that our thoughts are about, can cope with. Since, for the Russellian, the two aforementioned sentences express the same proposition, and belief for the Russellian is a relation between a subject and a proposition,

it follows that it is impossible for the two sentences ‘Ralph believes that George Eliot is a novelist’ and ‘Ralph believes that Mary Ann Evans is a novelist’ to differ in truth-value. Philosophers of a Fregean bent, however, argue that they can differ in truth-value – that such a difference in truth-value is required, for example, to explain the linguistic and nonlinguistic behaviour of agents – and that the Russellian theory must therefore be wrong. Russellians have offered systematic replies to these arguments (Salmon, 1986; Soames, 1987; Braun, 1998) but the debate remains open.

The Fregean conception of propositions exhibits perhaps the finest grain and is thus able both to distinguish among necessarily equivalent propositions (like the Russellian account but unlike the unstructured possible world account) and to allow for a difference in truth-value between the two foregoing belief sentences. Because the constituents of propositions are modes of presentation (or concepts or “senses”) of the things that our beliefs are about, and modes of presentation are many-one related to these things, there will be many more modes of presentation than the things they are modes of presentation of; and so the requisite fineness of grain necessary for distinguishing between the propositions expressed by the sentences ‘George Eliot is a novelist’ and ‘Mary Anne Evans is a novelist’ will be achieved. Since these two sentences express different propositions due to their different conceptual constituents, it is possible for a person to believe the proposition expressed by one but not to believe the proposition expressed by the other.

This extra fineness of grain is bought at a certain cost, however, for it seems that the propositional grain is perhaps now too fine for propositions to play the role of the linguistic meanings of sentences. Arguably, since, for example, ‘attorney’ and ‘lawyer’ are synonyms, the sentences ‘Lawyers are wealthy’ and ‘Attorneys are wealthy’ are synonymous, that is, have the same meaning. They should therefore express the same propositions (if propositions are supposed to be the meanings of sentences). Yet, it seems possible for a person to believe that lawyers are wealthy, but to doubt whether attorneys are, indicating for the Fregean that the two sentences express different propositions. If the linguistic meanings of sentences are more coarsely grained than the cognitive contents of thoughts according to the Fregean, it is not clear whether a single thing – a proposition – can play both roles.

The Fregean theory is also incomplete in a way that the Russellian theory is not, and this takes us back to the ontological question of what propositions *are*, as opposed to the question of how best to represent

them. The Russellian has a clear account of what the constituents of propositions are: the ordinary objects, properties, and relations that our thoughts and sayings are about. For the Fregean, however, the constituents of propositions are sense or modes of presentation or concepts of the things that our thoughts and sayings are about. Yet, what are these modes of presentation, these senses? All attempts to say what they are have been subjected to powerful and sustained criticism, and for this reason it is not clear whether the Fregean theory can ever be completed (Schiffer, 2003).

However, just because the Russellian has an account of what propositional constituents are does not mean that the Russellian theory is complete. For the Russellian theory suffers from the lack of any account of what binds propositional constituents together to form a unity, rather than a loose collection of unrelated parts. How is a proposition distinguished from a mere *list* of items? Frege (1892b) himself held that the key to this question was to be found in the nature of the propositional constituents themselves: At least one of them is always “incomplete” or “unsaturated” and is “completed” or “saturated” by the other constituents, which are themselves already complete or saturated. Russell (1913) struggled heroically for many years, indeed decades, to solve this “binding” problem or “the problem of the unity of the proposition” (a problem first stated by Plato in *The sophist*) without ultimate success. Contemporary Russellians, however, have been more concerned with the construction of formal semantic theories that invoke model-theoretic representations of propositions than with the metaphysical question of what binds or glues propositional constituents together into a propositional unity. This difficult and ancient question is once again beginning to receive the attention it deserves (Gaskin, 1995; King, 1995; Jubien, 2001; Gibson, 2004).

Quantifiers: Semantics

E L Keenan, University of California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

During the past 25 years, our empirical and mathematical knowledge of quantification in natural language has exploded. We now have mathematically precise (if sometimes contentious) answers to questions raised independently within generative grammar, and we are able to offer many new generalizations. We review these results here. For extensive overviews, see Westerståhl (1989), Keenan (1996), and Keenan and Westerståhl (1997). Some important collections of articles are van Benthem and ter Meulen (1985), Reuland and ter Meulen (1987), Gärdenfors (1987), Lappin (1988), van der Does and van Eijck (1996), Szabolcsi (1997), and from a mathematical perspective, Krynicki *et al.* (1995).

The best understood type of quantification in natural language is that exemplified by *all poets* in *All poets daydream*. We treat *daydream* as denoting a property of individuals, represented as a subset of the domain E of objects under discussion. Quantified Noun Phrases (NPs) such as *all poets* will be treated as denoting functions, called ‘generalized quantifiers,’ which map properties to truth values, True (T) or False (F). For example, writing denotations in bold-face, **all poets** maps **daydream** to True (over a domain E) if and only if the set of poets is a subset of the set of objects that daydream. Interpreting Dets (Determiners) as functions from properties to generalized quantifiers, we give denotations for many quantifiers in simple set theoretical terms. We write $X \subseteq Y$ to say “X is a subset of Y,” $X \cap Y$ for “X intersect Y,” the set of objects that lie in both X and Y; $X - Y$ for the set of objects in X that are not in Y, and $|X|$ for the number of elements in X.

- (1a) **ALL**(A) (B) = T iff $A \subseteq B$
- (1b) **(THE TEN)** (A) (B) = T iff $|A| = 10$ and $A \subseteq B$
- (1c) **NO**(A) (B) = T iff $|A \cap B| = 0$
- (1d) **SOME**(A) (B) = T iff $|A \cap B| > 0$
- (1e) **NEITHER**(A) (B) = T iff $|A| = 2$ & $|A \cap B| = 0$

$$(1f) \text{ (FEWER THAN TEN) (A) (B) = T iff } |A \cap B| < 10$$

$$(1g) \text{ (ALL BUT ONE) (A) (B) = T iff } |A - B| = 1$$

$$(1h) \text{ MOST(A) (B) = T iff } |A \cap B| > |A - B|$$

To test that the definitions above have been properly understood, the reader should try to fill in appropriately the blanks in (2).

$$(2a) \text{ (AT LEAST TWO) (A) (B) = T iff } \underline{\hspace{2cm}}$$

$$(2b) \text{ BOTH(A) (B) = T iff } \underline{\hspace{2cm}}$$

$$(2c) \text{ (AT MOST FIVE OF THE TEN) (A) (B) = T iff } \underline{\hspace{2cm}}$$

$$(2d) \text{ (LESS THAN HALF THE) (A) (B) = T iff } \underline{\hspace{2cm}}$$

We concentrate on NPs of the form [Det + N], but we should point out three further classes of generalized quantifiers denoting NPs: first, lexical NPs, notably proper nouns such as *John* and *Mary*; second, boolean compounds in *and*, *or*, *neither ... nor ...* and *not*, as in *Neither John nor Mary* (came to the party), *Sue and some student* set up the chairs, *not more than two students* attended the lecture. And third, NPs built from Dets that combine with two Nouns to form an NP (Keenan and Moss, 1985; Beghelli, 1993): *more students than teachers* (signed the petition), *exactly as many students as teachers* signed, etc. The interpretation of *more ... than ...* is given by:

$$(3) \text{ For all properties A,B,C (MORE A THAN B) (C) = T iff } |A \cap C| > |B \cap C|$$

The reader may want to write out the definitions of two place Dets such as **FEWER ... THAN ...**, **TWO MORE ... THAN ...**, **TWICE AS MANY ... AS ...**, **THE SAME NUMBER OF ... AS ...**

Standard Quantifiers: Some Linguistic Generalizations

We consider cases where the quantifier semantics sketched above has proven enlightening in formulating linguistic generalizations. As a first case, observe that in (4a) the presence of *ever*, called a ‘negative polarity item (npi),’ is ungrammatical; in (4b) it is fine.

- (4a) *Some student here has ever been to Pinsk.
 (4b) No student here has ever been to Pinsk.

Similarly *any* in *No child saw any birds on the walk* is an *npi*, not licensed in **Some child saw any birds on the walk*. **The linguistic query:** Which NPs in contexts like (4) license *npi*'s? To within a good first approximation, the answer is given by the Ladusaw-Fauconnier Generalization (Ladusaw, 1983): *The NPs which license npi's are just those which denote decreasing (order reversing) generalized quantifiers*. A generalized quantifier *F* is *decreasing* iff whenever $A \subseteq B$ then if $F(B) = T$ then $F(A) = T$. **No student** is decreasing since if all *As* are *Bs* ($A \subseteq B$), then if no student is a *B*, it follows that no student is an *A* (otherwise that student would also be a *B*, contrary to assumption). In contrast, **some student** is not decreasing: perhaps all *As* are *Bs* and there are many students among the *Bs* but they all lie among those that are not *As*. The reader can verify that the following NPs are decreasing and do license *npi*'s: *fewer than five students, less than half the students, not more than two students, neither John nor Bill, no student's doctor*. In contrast, NPs such as *John, more than five students, most poets, either John or Bill, some student's doctor* are not decreasing and do not license *npi*'s. Keenan and Szabolcsi (see **Boole and Algebraic Semantics**) point out that standard negation is also a decreasing function, and it also licenses *npi*'s: **John has ever been to Pinsk* vs. *John hasn't ever been to Pinsk*.

Our first generalization also illustrates that whether an NP of the form [Det + N] is decreasing or not is decided by the Det. So if *no student* is decreasing then, so is *no child, no professional acrobat*, etc. since they all have the same Det. Similarly if *some student* is not decreasing, then neither is *some child, some professional acrobat*, etc.. Many linguists refer to the expressions we call NPs as DPs ('Determiner Phrases'), in part because significant properties of the entire expression, such as whether it is decreasing or not, is decided by the choice of Det. (But other properties, such as whether the expression is animate, feminine, or satisfies the selection restrictions of a predicate, are determined by the N. #*Every idea laughed* is bizarre, since ideas aren't the kinds of things that can laugh and changing the Det does not improve matters: #*Some idea laughed, #Most ideas laugh*).

As a second generalization, consider how we may characterize the NPs that are *definite* (plural) in the sense that they may grammatically replace *the poems* in *two of the poems*. Some such NPs are *the ten poems, these (ten) cats, John's (ten) students*. Some NPs that are not definite (plural) in this sense are: *no poems, every cat, most students*. Again, to within a

first approximation, we may say that the definite plural NPs are those of the form [Det + N], where (in each domain) Det denotes a function *f* that satisfies:

- (5) For all *A*, either $f(A)(B) = F$; all *B*, or for some $X \subseteq A$, $f(A)(B) = T$ iff $X \subseteq B$.

To illustrate the idea, **(John's ten) (students)** maps each set *B* to *F* if John does not have exactly ten students; if he does, then it maps a set *B*, such as **daydream in class** to *T* iff the property of being a student-which-John-has is a subset of *B*. See Barwise and Cooper (1981) and Matthewson (2001) for further discussion.

The two generalizations adduced so far are semantic characterizations of syntactic phenomena. For purposes of defining the class of well-formed expressions in English, we need to know which NPs license *npi*'s in the predicate and which may occur naturally in the post of position in partitives. Most approaches to generative grammar desire a purely syntactic definition of these classes. Our observations do not rule out such definitions. Indeed, they provide a criterion for whether a proposed definition is adequate or not. Still, at the time of writing, we have no explicit syntactic definition of these two classes of NPs.

A third problem comparable to our first two is to characterize those NPs that occur naturally in *Existential There* (ET) contexts, as in (6).

- (6a) There are/aren't *more than ten boys* in the room.
 (6b) *There are/aren't *most boys* in the room.

This problem has vexed generative grammarians since Milsark (1977). See Reuland and ter Meulen (1987) and Keenan (2003). Part of the problem is that affirmative declarative Ss of the form in (6) have a variety of uses, with different uses seemingly allowing different NPs. For example, in so-called 'list contexts' (Rando and Napoli, 1978), ET sentences admit definite NPs such as *the bus* in *How can I get to UCLA from here? Well, there's always the bus, but it doesn't run very often*. But mostly these uses are not preserved in negative or interrogative Ss. Putting aside uses limited to affirmative declarative Ss, Keenan (2003) supports that NPs that occur freely in ET contexts are ones built from Dets that denote a certain kind of 'conservative' function. A Det is, standardly, **conservative**, or as we shall say here, **conservative on its first argument**, if it satisfies (7a), stated more generally in (7b).

- (7a) Det poets daydream iff Det poets are poets who daydream
 (7b) $D(A)(B) = D(A)(A \cap B)$

To see that *most but not all* is conservative, for example, check that *Most but not all poets daydream*

and *Most but not all poets are poets who daydream* always have the same truth value. Indeed, the second sentence seems redundant, with the predicate just repeating information already contained in the Noun argument.

The formulation in (7b) says that in evaluating the truth of $D(A)(B)$, we may limit the predicate argument B to those of its elements that occur in A . In this sense, then, we shall say that D is CONS1, ‘conservative on its first argument.’ And we support:

(8) Cons in general Dets denote CONS1 functions

Cons is a new generalization, not one that arises directly in response to a query from independent linguistic study. It is surprisingly strong. Given a domain E with n elements, Keenan and Stavi (1986) show that for $k = 4^n$ there are 2^k functions from pairs of properties to $\{T, F\}$. Only $2^{k'}$ of these functions are Cons, where $k' = 3^n$. So in a domain with just two individuals, there are $2^{16} = 65,536$ maps from pairs of properties to truth values, only $2^9 = 512$ of which are conservative! So Cons rules out most logically possible denotations for Dets. Here is a simple non-conservative function, F : $F(A)(B) = T$ iff $|A| = |B|$. Clearly $F(\{a, b\}, \{a, c\}) = T$, but $F(\{a, b\}, \{a, b\} \cap \{a, c\}) = F(\{a, b\}, \{a\}) = F$, so F fails Cons.

Now, mathematically it makes sense to ask whether there are Dets that are conservative on their second, predicate, argument. Such Dets would denote functions D satisfying $D(A)(B) = D(A \cap B)(B)$, where we can limit the A s we consider to those that lie in B . Many natural classes of Dets fail CONS2. For example, **universal** Dets, such as *all*, *all but ten*, *every...but John*. It might be false that all poets daydream, but it must be true that all poets who daydream daydream. So *all* is not CONS2. Also not CONS2 are **definite** Dets, such as *the*, *the ten*, *these (ten)*, *John’s (ten)*; and **proportional** Dets, such as *most*, *half (of) the*, and *not one...in ten*. But there is one large class of Dets that are CONS2. They include the *intersective* Dets, ones whose values just depend on which objects have both the Noun property and the Predicate property. For example, *some* is intersective since the truth of $SOME(A)(B)$ is decided just by checking $A \cap B$ (verifying that it is not empty). Let us define:

(9) D is *intersective* iff for all A, A', B, B' if $A \cap B = A' \cap B'$ then $D(A)(B) = D(A')(B')$

So intersective D s are ones ‘invariant’ under replacement of A and B with other arguments A' and B' provided the intersection of the pairs of arguments remains unchanged. Note that, an intersective D is necessarily CONS 1: since $A \cap B = A \cap (A \cap B)$ we infer $D(A)(B) = D(A)(A \cap B)$. And since $A \cap B =$

$(A \cap B) \cap B$, we have that $D(A)(B) = D(A \cap B)(B)$, and so intersective Dets are CONS2. In fact:

Theorem D is intersective iff D is CONS1 and CONS2 (Keenan, 2003)

An important special case of intersective Dets are **cardinal** ones, whose values depend on the cardinality of $A \cap B$, such as *at least n* , *more/fewer than n* , *at most n* , *approximately n* , *between n and m* , *several*, *a dozen*, *just finitely many*, and *infinitely many*. And we now answer our third query (Keenan, 2003):

(10) NPs which occur freely in Existential There contexts are (boolean compounds of) ones built from CONS2 Dets.

‘Boolean compounds’ here just refers to NPs built by conjunction, disjunction, and negation. For example, *There are at least two dogs and not more than five cats in the garden* is fine since *at least two dogs* and *more than five cats* both occur in ET contexts.

Example (10) predicts that NPs built from intersective Dets occur in ET contexts, and this is correct: *Aren’t there between five and ten students in your class?* *Was there no student (but John) in the building?* etc. (Note that **no...but John** treated as a Det is intersective, as *No A but John is a B* is True iff $A \cap B = \{\text{John}\}$, that is, the only A that is a B is John). Similarly, the universal, definite, and proportional Dets noted earlier are predicted not to occur freely in ET contexts since they fail CONS2, and this is correct: **Weren’t there all/most/the students in the class?*

Are there are CONS2 Dets that fail to be intersective? By the theorem, they would have to fail to be CONS1, and so rather rare. But there are two candidates: NPs of the form [only/mostly N], such as *only poets*. Interpreting *only* as a Det yields $ONLY(A)(B) = T$ iff $B \subseteq A$. For example, *Only poets daydream* is true iff everyone who daydreams is a poet (but there may be poets who don’t daydream). Clearly $ONLY$ thus defined is CONS2, since $ONLY(A \cap B)(B) = T$ iff $B \subseteq A \cap B$, iff $B \subseteq A$. So (10) predicts the well-formedness of *There weren’t only poets at the party*, which is correct.

A last case covered, unexpectedly, by (10) are NPs built from comparative Dets like *more...than...* which combined with two N s to form an NP. Each N property is a conservativity domain. To evaluate whether *More students than teachers daydream* we must consider both the students who daydream and the teachers who daydream. But not only are comparative NPs conservative on their two N arguments; they are intersective, in fact, cardinal. To decide whether more A s than B s have C , we need only check $|A \cap C|$ and $|B \cap C|$, verifying that the former is greater than the latter. Thus, (10) predicts

that cardinal comparatives should occur in ET contexts, and they do: *Weren't there more students than teachers at the party?* (We can also compare predicate properties, as in *More poets drink than smoke*, in which case only the single N property is a conservativity domain).

A fourth linguistic generalization is given in (11), where 'lexical' means 'not syntactically derived.'

- (11) Lexical NPs are monotonic, and lexical Dets build monotonic NPs.

A monotonic NP is one that either denotes a decreasing function (already defined) or an increasing one, where a generalized quantifier *F* is **increasing** iff whenever $A \subseteq B$ then if $F(A) = T$ then $F(B) = T$. Lexical NPs, principally proper nouns (*John, ...*) and pronouns (*he, she, ...*), are easily seen to be increasing: to paraphrase Aristotle, if all poets daydream and Paul is a poet then Paul daydreams. The reader may verify that *all/some/most/the five/my/John's cats* are all increasing, so lexical Dets usually build increasing NPs. But *no* and *neither* build decreasing ones. The only slightly doubtful case are NPs built from bare numerals, such as *two poets*. The NP is increasing if *two* is understood in the sense of *at least two*; it is not monotonic if understood as *exactly two*. We find the *at least two* reading the most natural because in some cases that is clearly what is intended, as in *Are there two free seats in the front row?* Additional information from context can be invoked to force the *exactly two* reading. Our last generalization in this section is (12):

- (12) Natural Language Dets are Domain Independent

In practical applications, such as in database theory (Abiteboul *et al.*, 1995), it is important to know what the domain of objects is that properties under consideration are subsets of. It would be more accurate (van Benthem, 1984) to treat NPs, for example, as functions that associate with each possible domain *E* a generalized quantifier over *E*, a function associating with each subset *A* of *E* a truth value. Similarly Dets associate with each *E* a function mapping subsets of *E* to generalized quantifiers over *E*. But (12) says that the value a Det denotation *D* assigns to a pair *A, B* of properties cannot depend on the choice of underlying domain (as long as *A* and *B* are subsets of that domain). This (seemingly vacuous) constraint entails, for example, that natural languages could not present a Det *blik* defined by: *Blik As are Bs* is True iff the number of non-*As* is two. The truth value of such an *S* would vary with the domain: if $A = \{a\}$ and $E = \{a, b, c\}$ then it is True, but if $E = \{a, b\}$ it is False.

To close this section, we note that our treatment of NPs and Dets enables us to specify precisely certain traditional, if informally given, classes of expressions. We note two cases. First, the linguistic literature on quantification usually builds heavily on the specific quantifiers *some* and *all*, which we have already defined. But now we can see that they represent two quite general classes of Dets: the *Existential* ones, including *some*, are just those that denote intersective functions, as defined in (9). The *Universal* Dets are those that denote cointersective ones, as defined in (13).

- (13) *D* is *co-intersective* iff for all *A, B, X, Y* if $A - B = X - Y$ then $D(A)(B) = D(X)(Y)$

Thus, whether a cointersective function *D* is True of a pair *A, B* is decided just by checking $A - B$. To see that ALL is cointersective observe that, as defined, $ALL(A)(B) = T$ iff $|A - B| = 0$. (*ALL BUT TEN*) (*A*) (*B*) = *T* iff $|A - B| = 10$, etc. Our approach also enables us to see that proportionality Dets such as *most, half, more than one ... in ten*, etc., are more complicated than either intersective or cointersective Dets, because their truth at a pair *A, B* of properties depends on both $A \cap B$ and $A - B$.

Secondly, most of the Dets discussed in the linguistic literature are ones with a 'logical' or 'mathematical' sense: *some, every, most, most of the ten, not all, most but not all, between a third and two thirds of the*, etc. But we have also countenanced a few which are more 'empirical', such as *my, John's ten, no ... but John*, etc. (see Keenan, 1996). Can we say in precise terms what the distinction is? We can. The 'logical' Dets are those that are invariant under permutations of the elements of the underlying domain *E*. A permutation of *E* is simply a one-to-one function from *E* onto *E*. If *h* is such a function and *A* a subset of *E*, then by $h(A)$ is meant $\{h(x) | x \text{ in } A\}$. And we say that a generalized quantifier *F* is *permutation invariant* (PI) iff for all *A*, all permutations *h* of *E*, $F(A) = F(h(A))$. A Det function *D* is PI iff for all *A, B* and all permutations *h*, $D(A)(B) = D(h(A))(h(B))$. Note that, for any $X \subseteq E$, *X* and $h(X)$ always have the same cardinality. So the 'logical' quantifiers are those that cannot distinguish between properties *A, A'* of the same cardinality (and whose complements, $E - A$ and $E - A'$ have the same cardinality when *E* is infinite). One computes, then, that Dets such as *some, every, most, most of the ten, not all, most but not all, between a third and two thirds of the* always denote PI functions, whereas ones like *my, John's ten*, etc., do not.

Some Non-Standard Quantifiers

We begin by considering the interpretation of the quantified NPs already discussed when they occur as

objects of transitive and ditransitive verbs: *John envies all movie actors*, *He gave most of his teachers several presents*. Many semanticists regard these uses as illustrating a ‘type mismatch.’ To interpret the object NP in *John interviewed every applicant* we apparently need to treat it as a function mapping a binary relation (**interview**) to a property, but we are already committed to interpreting NPs as maps from properties (unary relations) to truth values (zero-ary relations). But in fact there is no problem here at all. We know exactly what property *interviewed every applicant* denotes. It is the set of objects x such that ‘ x interviewed every applicant’, that is, such that **every applicant** is true of the *set* of objects that x interviewed. In the last phrase, we are applying the generalized quantifier **every applicant** to a set – which is exactly how we have already been interpreting NPs. So the value that an NP denotation assigns to a binary (ternary, ...) relation is determined by the value that it assigns to sets (properties). So the solution to the ‘type mismatch’ problem is to treat NPs as directly denoting functions mapping $n+1$ -ary relations to n -ary ones in such a way that their values at $n > 1$ -ary relations are determined by their values at the unary relations. Here is the solution for binary relations. Keenan and Westerståhl (1997) give the general statement. We write aR for $\{b | aRb\}$, the set of objects that a stands in the relation R to.

- (14) A type $\langle 1 \rangle$ function F over a universe E maps each subset of E to a truth value and each binary relation R over E to a subset of E by:
 $F(R) = \{a | F(aR) = T\}$.

Clearly, then, each generalized quantifier uniquely determines a type $\langle 1 \rangle$ function; all we have done is add more objects (binary relations) to its domain. So the interpretation of an S with two quantified NPs is given compositionally, as in (15).

- (15a) No politician kissed every baby
 (15b) (no politician) ((every baby) (kissed))

Note that, (15b) means ‘No politician has the property that he kissed every baby,’ the object narrow scope (ONS) reading of (15a). In fact, (15a) does not have an object wide scope (OWS) reading, on which it would mean that every baby has the property that no politician kissed him. But some S s with two quantified NPs do present such ambiguities, a matter of much concern to linguists (Szabolcsi, 1997). *Some editor read every manuscript* has an ONS reading, representable analogously to (15b), on which it means that there is an editor with the property that he read every ms. But it also has a OWS reading, on which it means that every ms has the property that some editor read it – so the editors may vary with the manuscripts. An easy use of

variable binding operators (VBOs) allows us to represent the less accessible OWS reading by:

- (16) (every manuscript x) ((some editor) (read x))

The use of VBOs has distracted us from the fact that the range of logically possible interpretations of nonsubject NPs is vastly greater than of subject NPs. Given a universe E with more than one element, there are many more functions from binary relations to properties than there are from properties to truth values. And natural languages provide the means for denoting some of these. To see this, we need a way to test functions H from relations to properties to see if they are possibly extensions of functions from properties to truth values. Here is such a test, given first by example, where we test X :

- (17a) If John praised exactly the people who Bill criticized then John praised X iff Bill criticized X
 (17b) If $aR = bS$ then $a \in F(R)$ iff $b \in F(S)$

For example, *most of the Peter’s students* passes the X test in (17a). Given the truth of the *if*-clause, we infer that *John praised most of Peter’s students* and *Bill criticized most of Peter’s students* have the same truth value. (This is hardly surprising; the NP we are testing occurs as a subject of a P1 and thus is interpretable as a generalized quantifier.)

But consider now the reflexive pronoun *himself*. It fails the test. Imagine, for example, that the *if*-clause is true and that John praised just Sam, Frank, Bill, and Sue. Then those are just the people that Bill criticized, so *Bill criticized himself* is true, but *John criticized himself* is false. Hence, there is *no* function from properties to truth value that takes exactly the value on binary relations as *himself* does. That is, reflexives represent an increase in logical expressive power. Moreover *himself* is not unique here; all (nontrivial) referentially dependent NPs in object position are logically new in this sense. This includes ones like *everyone but himself*, *both himself and the teacher*, *everyone smarter than himself* (as in *John criticizes everyone smarter than himself*) in which the NP must be referentially dependent, as well as NPs like *his mother* where it simply may be dependent. It is the dependent interpretation where it is new.

The increase in logical expressive power afforded by nonsubject NPs is far more extensive than instantiated by the referentially dependent NPs. They are not functions of type $\langle 1 \rangle$, but they can be correctly interpreted as functions from binary relations to sets, (just not ones that extend appropriately a generalized quantifier). But the sort of dependency in (18) cannot be handled in a comparable way:

- (18) Different people like different things

The weakest truth conditions of (18) are easy to state: for any two (different) people x and y , the set of things that x likes is not identical to the set that y likes. And we know (Keenan, 1996) that over any domain with several people and things, there are *no* type $\langle 1 \rangle$ functions F and G such that for all binary relations R , $F(G(R))$ is true iff different people stand in the relation R to different things. Similar claims hold for other S s which involve comparing different object sets with different choices of subject argument: *John and Bill support rival political parties*, *Rosa and Zelda date men who dislike each other*, etc. In fact, the same claim holds even when the comparison is not one of difference: *All the students answered the same questions on the exam*, *They wore the same color necktie*, etc. Speaking very informally, we can say that the combination of subject and object expressions in these S s place conditions on the relation denoted by the transitive verb which are inherently ‘relational,’ not expressible as independently statable conditions on each argument. To state this more explicitly, let us define:

- (19) A function H from binary relations to truth values is said to be of type $\langle 2 \rangle$. Such a function is type $\langle 1 \rangle$ *reducible* iff there are type $\langle 1 \rangle$ functions F, G such that for all binary relations R , $H(R) = F(G(R))$.

Then what we are saying above is that the type $\langle 2 \rangle$ functions expressed by (Different people, different things), (John and Bill, rival political parties), etc., are not type $\langle 1 \rangle$ reducible. Thus, they are not expressible as the composition of two generalized quantifiers, and so are logically new. Some additional examples are induced by the *else-else* construction in (20), the *which-which* construction in (21), reciprocal objects in (22), and predicate anaphors in (23). For further examples, see Keenan (1996).

- (20) John didn’t praise Bill but everyone else praised everyone else.
John praised Bill but no one else praised anyone else.
- (21) John doesn’t know which students answered which questions on the exam.
- (22) The students were shouting at each other.
- (23) John read more books than Bill (did).

In sum, we have a list of expression types that are not type $\langle 1 \rangle$ reducible, but we do not know precisely what type $\langle 2 \rangle$ functions are expressible. All of them (over finite E)?

Thus, much remains to be discovered even in English, the language in which quantifiers have been the most extensively studied. And we are really just beginning to study quantification in less well known

languages (Bach *et al.*, 1995; Matthewson, 2001) as well as in contexts other than that of NPs and Dets, the most prominent here being temporal and event quantification, using adverbial quantifiers, as in *Matt always/often/occasionally/seldom/rarely/never visits museums on weekends* (de Swart, 1996).

Answers to Exercises

(AT LEAST TWO) (A) (B) = T iff $|A \cap B| \geq 2$

BOTH(A) (B) = T iff $|A| = 2$ and $A \subseteq B$

(AT MOST FIVE OF THE TEN) (A) (B) = T iff

$|A| = 10$ and $|A \cap B| \leq 5$

(LESS THAN HALF THE) (A) (B) = T iff

$|A \cap B| < |A|/2$

Radical Interpretation, Translation and Interpretationalism

M Hymers, Dalhousie University, Halifax, Nova Scotia, Canada

© 2006 Elsevier Ltd. All rights reserved.

Donald Davidson's idea of **radical interpretation** gets its inspiration from W. V. Quine's account of **radical translation**. This article will deal first with Quine's view and then Davidson's before turning to the **interpretationalism** of Davidson's views and criticisms of thereof.

Radical Translation

W. V. Quine is generally suspicious of such mental notions as belief, intention, and meaning, preferring an austere behaviorist account of language use. Quine imagines a field linguist attempting to compile a **translation manual** that would pair sentences of her own language with sentences of a language wholly unlike any she has ever encountered, unaided by dictionaries or local interpreters. In this scenario of **radical translation**, the linguist has access only to the bodily behavior of the speaker and to those objects and events that are manifest in the local environment. The best pragmatic procedure for the radical translator to follow, thinks Quine, is to try to correlate the speaker's utterances with their proximal stimuli – “surface irritations” (Quine, 1960: 22) of sensory receptors. If a given stimulus—say, that produced by a rabbit—can be correlated with a given utterance on one occasion – say, ‘Gavagai!’ – then the translator must try to reproduce similar stimuli in order to see whether they provoke similar utterances (find some more rabbits and point them out). Or, better, the translator may on various stimulus-occasions, similar and different, repeat the speaker's original utterance in the hope of eliciting terms for assent and dissent (point to rabbits and rutabagas alike, asking, ‘Gavagai?’). With a firm working hypothesis about these terms in hand, she may proceed to pair sentences of the speaker's language with sentences of her own language, according as they seem from her perspective to have the same **stimulus meanings** – that is, roughly, to be

prompted by the same sorts of events and objects. Hypotheses concerning assent and dissent may, of course, meet with disconfirming evidence, forcing the translator to begin anew with another hypothesis. But by following this procedure, Quine thinks, the field linguist can expect eventually to translate **observation-statements** – reports on observable occurrent events or states of affairs. By applying a **principle of charity**, which counsels the translator not to assume wanton irrationality on the speaker's part, she may also hope to translate logical terms, such as ‘not,’ ‘and,’ and ‘or,’ since a rational speaker is unlikely to affirm each conjunct of a conjunction (‘Roses are red’ and ‘Violets are blue’) without also affirming the conjunction (‘Roses are red, **and** violets are blue’). Efforts to take radical translation further to relatively nonobservational sentences – such as ‘Electrons have negative charge’ or ‘Incest is an abomination’ – will rely on the formulation of **analytical hypotheses** regarding how to parse the speaker's utterances into words and other sub-sentential components. However, Quine contends, there will always be rival systems of analytical hypotheses, any of which will be as pragmatically successful as the other for purposes of compiling a workable translation manual. Translation is thus indeterminate, but Quine thinks that the lessons of radical translation apply with equal justice to our attempts to converse with our colinguists and to our learning of our own language. Having learned the language already, we find the procedure of interpreting our fellow speakers and ourselves as familiar as can be, but in neither case do we have any more evidence to go on than is available to the field linguist. It follows, thinks Quine, that meaning itself is no more determinate than translation (*see Indeterminacy, Semantic*).

Radical Interpretation

In the work of Donald Davidson, radical translation is transmuted into **radical interpretation**. The two notions differ in at least three important respects. (1) Whereas the former notion rests on methodological behaviorism, the latter does not. (2) Whereas radical translation aims to compile a translation

manual for the language under study, radical interpretation aims to formulate and test, as part of a general theory of interpretation for a speaker, a core meaning theory for the speaker's language, which will describe the finite vocabulary of the language and show how that vocabulary can be combined using a finite set of recursive rules to produce any sentence in the language. Knowledge of such a theory would supposedly "suffice" (Davidson, 1984: 172; 1986: 438) for understanding the speaker, but is not necessary (1984: 125; 1986: 438). (3) Whereas radical translation relies on the principle of charity methodologically to argue for the translatability of logical connectives, radical interpretation applies this principle generally as something like a necessary condition of the very possibility of interpretation (Ramberg, 1989: 77). These points need elaboration.

(1) Quine focuses on terms for assent or dissent "because they suggest a behaviouristic test," but Davidson has no such commitment to behaviorism (Davidson, 1984: 231). He criticizes Quine's preoccupation with proximal causes of sensory stimulation, arguing that Quine slips back into a Cartesian model of the mind as isolated from the world, thereby exposing himself to both an "old-fashioned skepticism of the senses" (Davidson, 1990: 74) and a relativism about truth that arises from the fact that no two individuals share the same patterns of sensory stimulation (1990: 76). Translation even of observation sentences, which Davidson does not distinguish sharply from theoretical sentences (2001: 149) can be assured to work only if the interpreter focuses on macroscopic objects and events in a world shared by interpreter and speaker – marmots and mangoes, instead of photons striking nerve endings. In order to locate the source of the speaker's sensory stimulations, we need, says Davidson, three patterns of similarity from one occasion to another: the similarity I find in my experiences, the similarity the speaker finds in her experiences, and the similarity that I find in the speaker's responses to her experiences (2001: 119). The interpreter must "correlate his own responses and those of the speaker by reference to the mutually salient causes in the world of which they speak" (1990: 78) – a process Davidson analogizes to 'triangulation' (2001: 105). (See 'Interpretationalism' below for more on this process.)

(2) The notion of translation does not by itself, thinks Davidson, give a plausible account of meaning for the speaker's language. A better account would have to show systematically how "the meanings of sentences depend upon the meanings of words" (2001: 17) if a speaker's capacity to understand and produce a potential infinity of novel and banal utterances is to be represented (*see Compositionality:*

Philosophical Aspects). Drawing on the formal logical work of Alfred Tarski (1949), Davidson proposes that we begin the task of interpretation by taking as basic the attitude of holding a sentence true (or false). Then, having identified the sentences a speaker holds true, we must formulate hypotheses about what finite vocabulary and what rules of syntax are operating in the speaker's language, and what rules of satisfaction are descriptive of the various predicates in the language. (A rule of satisfaction tells us what things satisfy a given predicate – roughly, of what things that predicate is true. It tells us which are the blue things or the koalas, for example.) Such a procedure provides a "model" (Davidson, 1986: 438) of what we commonly do when interpreting a speaker, though we cannot be plausibly said to **know** any such theory of interpretation (1986: 438). What exactly this means has occasioned some puzzlement (see Dummett, 1975, 1976; Schiffer, 1989: 116–117).

(3) This procedure requires that we be able to identify which sentences a speaker holds true, but this by itself will not tell us what those sentences mean. If we knew what the speaker believed in the circumstances, then that would give us some substantial clues concerning what she means by her sentences. However, our surest way of identifying what a speaker believes is by first knowing what her words mean. To escape this endless circle, Davidson appeals to the principle of charity, which, in his formulation, has it that we should "assume general agreement on beliefs" (1984: 196) and "try for a theory that finds [the speaker] consistent, a believer of truths, and a lover of the good (all by our own lights, it goes without saying)" (1980: 222). This is not a principle that we choose simply in order to avoid making our speaker sound "silly" (Quine, 1960: 59). Rather, "charity is forced on us" (Davidson, 1984: 197) if we are to be in a position to interpret our speaker **at all**.

Davidson believes that meaning- and attitude-attribution are holistic by nature. There is no sense to the idea of attributing a belief to a creature unless one attributes "a world of further beliefs to give it content and identity" (Davidson, 2001: 98) and likewise no way of assigning meaning to a sentence in isolation from assignments of meaning to other sentences (1980: 239). Such holism entails the possibility of reassigning meaning and content, so long as one makes compensating adjustments elsewhere in the attributed set of background meanings and beliefs. Thus Davidson allows for an indeterminacy of interpretation that is the "semantic analogue of Quine's indeterminacy of translation" (1984: 225), but as a consequence of his broader application of the principle of charity, he believes that "the range of indeterminacy is less than Quine thinks it is" (1984: 228).

What indeterminacy remains is, in Davidson's view, comparable to the possibility of adopting different scales of measurement for the same objective phenomenon, much as we may measure temperature on the Fahrenheit or Celsius scales (1984: 154, 225; 1980: 257; 2001: 145). Additionally, Davidson regards it as a facet of linguistic competence that one has "first person authority" (2001: 3) concerning the meanings of one's own words and the contents of one's own thoughts. So, unlike Quine, he does not think radical interpretation "begins at home" (Quine, 1969: 46) (though it might begin next door when one interprets one's colinguists).

Interpretationalism

Davidson's account of radical interpretation is readily coupled to a view about meaning and intentional content known as **interpretationalism**. Much as Quine maintains that translation is prior to meaning and not vice versa, as we might have thought prereflectively, Davidson contends that there is no fact concerning what a speaker's words mean or what the contents of her intentional attitudes are apart from the possibility of their meaning or content being attributed by an interpreter. This is because, as we saw briefly above, interpreting a speaker requires identifying the mutually salient causes of her verbal behavior. Any link in the causal chain extending from a publicly observable object to the surface irritations of her sensory organs could, on some account, be identified as the cause if the speaker is left to try to interpret herself. From a third-person point of view, however, what seems explanatory of the speaker's behavior is her pattern of responses to public objects, to which we also respond. "It takes two points of view to give a location to the cause of a thought, and thus to define its content" (Davidson, 2001: 212–213).

Criticisms of Radical Interpretation and Interpretationalism

Critics of interpretationalism may accuse it of an implausible instrumentalism about the mental (Davidson, 2001: 70; Hookway, 1988: 181), according to which intentional attitudes are no more than convenient fictions that we employ when trying to predict and explain the behavior of a rational creature. Furthermore, interpretationalism seems to lead to a vicious regress, since one's possession of meanings and intentional attitudes requires being interpreted by another, whose intentional attitudes, in turn, must be derived from the interpretations of a third, and so on (Heil, 1998: 131). Similar criticisms

are made of Daniel Dennett's "intentional stance" (1971; 1987) – see Putnam, 1987: 15–16; Rudder-Baker, 1989: 305 – a variety of "selective instrumentalism" (Dennett, 1987: 72), which Dennett distinguishes from "interpretationism" (1987: 15) and "classical instrumentalism" (1987: 71). Davidson (2001: 82) thinks that Dennett confuses the question of whether intentional attitudes are entities with the question of whether there are correct answers about what intentional attitudes anyone has. But Davidson replies here that his account is no more instrumentalist than are systems of measurement (2001: 74–75). The fact that we can measure temperature differently in Fahrenheit or Celsius does not show that no objective phenomenon is being measured; Dennett makes a similar response to the parallel criticism of his view (1987: 34). And the apparent regress arises only if we fail to see practices of interpretation as coming into being gradually and socially, producing interpretative communities "once they reach an appropriate level of sophistication" (Heil, 1998: 153).

Critics have doubted Davidson's ability to account for the meanings of sentences that, intuitively, are neither true nor false, such as interrogatives and imperatives, and, perhaps more seriously, of such sentences as direct and indirect quotations and attributions of intentional attitudes. (Tarski himself thought that his treatment of truth, from which Davidson borrows, could not be applied to natural languages.) Davidson has long recognized that there are programmatic challenges of this sort for his view to meet (1984: 35–36) and has taken an optimistic view of his chances, viewing the problems as a series of puzzles to be dealt with by an active research program (see the various essays in Davidson, 1984), though many critics remain pessimistic (Glock, 2003: 159–165; Schiffer, 1989).

Davidson's use of the principle of charity has also been criticized on a number of grounds. Some think it smacks of cultural imperialism, forcing us to construe cultural others as like their interpreters in all essential respects (MacIntyre, 1985). Davidson may respond that meaningful disagreement requires a broad background of agreement and that cultural difference cannot even be recognized without starting with something like the principle of charity (1984: 196–197; 2001: 39–41, 148–149). Some critics have suggested that charity is not sufficient for interpretation, since we have reason not to attribute what we take to be true beliefs to a speaker if it would be mysterious how she came to hold such a belief (Grandy, 1973: 445), and have proposed in its place a "principle of humanity" (Grandy, 1973: 443) according to which we should attribute beliefs that we would find it

reasonable to hold in the speaker's position. Davidson has responded with attempts to clarify the principle of charity (1984: xvii, 136) and with a proposal to distinguish two principles, Coherence and Correspondence (2001: 211). Others contend that it is shared behavior, not merely agreement in beliefs, that makes interpretation possible and that successful interpretation can thus succeed in the absence of charity (Glock, 2003: 194–199), but although such behavioral commonality may not be premised in the principle of charity, Davidson seems to agree that it is of central importance (2001: 128–129, 212–213), and the difference here is **perhaps** one of emphasis.

Realism and Antirealism

K Green, Monash University, Melbourne, Australia

Realism and antirealism in semantics can take a variety of forms, which are catalogued at the conclusion of this article. First, since realism looks like a metaphysical doctrine, it is necessary to set out how it relates to semantics. Some have claimed that since realism and antirealism concern metaphysics, they have little to do with semantics, truth, meaning, or

reference. Michael Devitt and Kim Sterelny argue that realism has two components: it is a doctrine about what exists and a doctrine about the nature of that existence. The realist about commonsense physical objects claims that they exist and that the nature of their existence is to exist independently of the mind. Devitt and Sterelny contrasted this realism with idealism: the view that while ordinary physical objects exist, their nature is to exist 'in the mind' in such a way that their existence is mind dependent (1999: 234–235). These doctrines, Devitt and

Sterelny argued, have nothing to do with semantics, for they can be stated without reference to semantic vocabulary such as 'meaning' or 'truth' (1999: 239). They position themselves as opposed to Michael Dummett, who has argued that the most illuminating way is to see them as implicitly hinging on differences in the theory of meaning (Dummett, 1978, 1991, 1992, 1993).

Realism does have two components, an existence component and one concerning the nature of that existence. Given this, antirealism, with regard to some range of entities, also has two forms. One denies existence. This is the antirealism of the atheist. The other denies mind independence, resulting in idealism and constructivism. In both cases, Dummett's contention, that the debate about what exists can be illuminated by seeing it as concerned with meaning and truth, appears correct. The traditional debate between idealists and realists arose from the skeptical questions posed by René Descartes in his *Meditations*. There Descartes wondered whether we know anything. Since in order to have knowledge one must have true beliefs, we could say that he wondered whether any of his beliefs were true. Descartes assumed that if his beliefs were true, they were made true by a reality that existed independently of him. Yet since he had access to that reality only through his 'ideas,' the question arose as to whether those ideas corresponded to anything, or were, like dreams, mere illusions. The idealists solved Descartes' radical skeptical problem by rejecting the gap between ideas and reality. The existence of the ideas themselves was taken to make our beliefs true. Formulated thus, the traditional distinction between realism and idealism can be seen to hinge on a dispute over what makes our beliefs true. Since it is all one whether we pose the skeptical problem directly for beliefs or think of it in terms of the sentences that express those beliefs, the metaphysical problem lends itself to a semantic formulation (Dummett, 1992: 132–134).

In his early writing, Dummett thought that the way to tackle the issue that divided realists from antirealists was to tackle the notion of truth directly, for he accepted, with Ludwig Wittgenstein, that the sentence is the smallest unit with which one can make a move in the language game and that therefore the notion of truth for sentences was primary (Dummett, 1973: 192–196). Looked at from the point of view of truth for sentences, the realist/antirealist debate hinges on whether truth is independent of us or is simply ideal warranted assertibility. A realist will say that truth is objective and independent of anything we do, but the price to pay for this is that there is no compelling reply to the skeptic. Also, if truth has nothing to do with our holding sentences

true, it can play no role in an account of the meaning of those sentences and is in danger of becoming an ungraspable we know not what. If, however, we want an account of truth that is central in a theory of meaning – which is a theory of what we know when we understand sentences – truth should be something we can grasp. Hence, Dummett analyzed truth in terms of warranted assertibility. As a result the principle of bivalence, which says that every meaningful assertoric sentence is either true or false, is given up. For there are sentences that are not justifiably assertible, yet it is not the case that we can confidently say that they are false, that is, that they will never be assertible. When the argument for antirealism directly concerns the notion of truth for sentences, it leads to questioning bivalence and the adoption of intuitionistic logic. But there are other arguments for antirealism that have a different character.

One variety of antirealism points to various speech acts that we can perform other than making truth-assessable statements. It claims that some sentences with which speakers appear to be making statements are not really descriptive utterances. So the possibility of a realist account of the truth of sentences for some area of discourse is excluded, because the discourse is not fact stating. The position of the expressivist in ethics, adopted by A. J. Ayer, is the paradigm of this form of antirealism (Ayer, 1946: 107). Like error theorists, who are discussed later in this article, expressivists suggest that we are in error about the actual semantics of our utterances. For them the realist's error lies in thinking that sentences of the disputed class describe facts.

Yet another issue divides realists about universals from nominalists. Like the realist about the physical world, the realist about universals at first appears to be making a metaphysical claim. It is that universals, as well as particulars, exist independently of us. As with realism about material objects, this claim can be seen to hinge on issues concerning that in virtue of which sentences are true. In order for the sentence 'The rose is red' to be true, one needs more than the mere existence of the particular rose being referred to. One needs it to be the case that the rose is red. If one understands this in terms of the rose instantiating the property of redness, one may be led to postulate the existence of universals, which are what general terms such as 'red' pick out. The nominalist, however, denies that one needs to explain the function of both singular and general terms by assigning a reference to them. According to Quine, for instance, singular terms refer, but predicates express their meanings; it is merely grammatical confusion that leads us to represent predication as a relation between two entities (Quine, 1970: 66–67).

The dispute over the existence of universals shows that not all forms of the realism/antirealism debate directly concern the notion of truth. What is at issue is often a question of the reference, or otherwise, of the subsentential parts of sentences. But these analyses flow naturally from questioning the nature of truth. Aristotle thought that both singular terms and general terms function by referring to, or picking out entities. Singular terms refer to objects; general terms refer to universals. On this model, a simple subject-predicate sentence is a string of names that is true just in case the object referred to by the singular term instantiates the universal referred to by the general term (Aristotle, 1984: 25–27). Bertrand Russell, puzzled by the meaningfulness of singular terms that fail of reference, proposed that in the vast majority of cases we can analyze names and definite descriptions, which appear to refer to objects, as really only involving descriptive phrases and quantifiers. ‘The rose on my table is red’ is then true just in case there is a unique thing that has the property of being a rose on my table as well as the property of being red (Russell, 1956). Dummett suggested that this is a move in the direction of antirealism (Dummett, 1991: 325). It is a semantic analysis that allows for the reduction of objects to bundles of properties.

Russell’s analysis of singular terms can be used to illustrate the way in which antirealism often takes a reductionist form. In 1904 Alexius Meinong proposed that ‘The golden mountain is golden’ is true in virtue of the subsistence of a nonexistent golden mountain to which the singular term ‘the golden mountain’ refers. Russell, objecting to a category of nonexistent existents, proposed that we reformulate the true sentence as saying that if anything is a golden mountain, it is golden. Russell was by no means an idealist, but in denying the existence of a referent of ‘the golden mountain,’ he went against the first component of a realist attitude to golden mountains. Similarly, the physicalist, being an antirealist about thoughts, will have to explain away the apparent truth of sentences such as ‘The terrifying thought stopped him in his tracks.’ A radical antirealist of the eliminativist slant might deem this sentence literally false. Alternatively, it could be treated as neither true nor false, because it is ill formed. But a reductionist antirealist with regard to thoughts will offer a paraphrase. This might take the form ‘Neurons playing the functional role of a warning of danger fired and stopped him in his tracks.’ Here the truth of the sentence involving an apparently nonreferring term is accounted for by offering a translation from which it is absent.

Both deeming some sentences neither true nor false because of failures of reference, and offering

reductionist paraphrases, constitute forms of antirealism of the broadly error-theoretic type. Error theory received its classic formulation in the work of Mackie (1977). The error theorist usually accepts that there is some range of sentences, typically sentences about physical things, for which the realist semantics holds. But the error theorist argues that we are led into error when we assume that the sentences of some other class share the same semantic structure. Mackie argued this for ethical statements. We are inclined to think of the semantic structure of the sentence ‘Charity is good’ as analogous to ‘Christ is good.’ If we accept the Aristotelian semantics sketched earlier in this article, this will involve thinking of charity as a kind of abstract object that instantiates the universal goodness. But these are queer kinds of entity. It is unclear how we have epistemological access to them, and it is arguable that we have been led to postulate their existence by an erroneous extension of the semantics of statements about physical objects. Adopting a version of this approach, Hartry Field argued, against the mathematical Platonist, that statements of mathematics that appear to involve truth grounded in reference to numbers really do no such thing and should not be deemed either true or false (Field, 1980: viii). When a person is persuaded on error-theoretic grounds that a realist semantics for some class of sentences is mistaken, but nevertheless wants to save the appearance of truth and falsehood for sentences of this class, he or she is characteristically forced to offer a reductionist account.

We can now construct a brief catalogue of forms of realism and antirealism. Global realism would treat all sentences realistically, and an ultra-global realist would accept not just classical logic but also the Aristotelian semantics according to which all singular terms refer to objects, while general terms refer to universals. Almost no philosopher is a global realist, and global antirealism is equally rare. Disputes arise in many areas. Platonists in mathematics oppose error theorists and constructivists; realists about mental entities oppose eliminativists and various forms of reductionist; realists about theoretical entities oppose instrumentalists; realists about commonsense material objects oppose phenomenologists and idealists; realists about possible worlds oppose ersatz theorists; realists in ethics oppose subjectivists, expressivists, and error theorists; realists about the past oppose presentists; and realists about the future oppose antirealists, for whom the future does not exist. Reductionist antirealism cannot be global, since it always involves a class of sentences interpreted realistically that provides a reduction class. Yet not all antirealism is reductionist. In the case of antirealism about the

future, there is a direct intuition that future-tense sentences are not now either true or false. Antirealists may deem some class of sentences to be nondescriptive, or descriptive but not involving a realist notion of truth. Among those who accept realist truth, there are those who analyze truth in terms of the existence of objects and universals, and others who take an antirealist attitude toward either objects or universals.

What Is Reference?

Reference is the relation that obtains between a use of a linguistic expression and what it stands for or denotes. Philosophical theories of reference aim to explain this relation. They address questions such as: Can we specify necessary or sufficient conditions for a use of an expression to single out some particular referent? What makes it the case that a sequence of marks or noises refers to what it does? What grounds the conventional word-referent relations that we take for granted in the unreflective course of linguistic communication?

Reference is a fundamental concept within the sub-discipline of philosophical inquiry that studies language and thought. It is intimately tied to some other core concepts, such as meaning, truth, and representation, and it lies at the root of various general philosophical issues. To cite a few illustrative examples (some of which are discussed later): [1] there is a venerable tradition of using data about referring expressions to support metaphysical and epistemological conclusions about their referents, running at

least from Aristotle's *Categories* through to many influential 20th-century works; [2] the ancient problem of nonbeing – cf. Plato's *Parmenides* for a classic discussion, and Lewis (1986) for discussion of some contemporary variants – is in part a problem about reference to nonactual, or nonconcrete, objects; [3] reference plays a central role in some of the most provocative and broad-ranging recent work in philosophy, including in particular the varieties of externalist arguments spurred by Kripke (1972) and Putnam (1975).

Proper names take center stage in debates about reference, as names are explicitly introduced to refer to specific individuals. Other much-discussed, basic cases of reference include uses of demonstratives (such as 'that duck') and indexical pronouns ('she') to refer to individuals which the speaker currently has in mind. Beyond these paradigm cases, though, there is not much uncontested ground. For example, there are long-standing debates over whether definite descriptions – expressions of the form 'the F' – should be classified as referring expressions (for discussion, *see Descriptions, Definite and Indefinite: Philosophical Aspects*).

In addition to such differences of opinion, there also are significant differences of usage. In its strictest sense, 'reference' applies only to the relation between singular terms (such as names and pronouns) and

what they are used to single out. On this usage, 'reference' names the simplest sort of word-object relation; and whatever the semantic relations are, precisely, that are involved in, say, general terms ('justice') or predicates ('is tall'), they are distinct from reference. In a broader sense of the term 'reference,' any expression that makes a difference to the truth-conditions of sentences in which it occurs thereby has a referent – general terms refer to universals, predicates refer to properties, and so on. So, in the former, strict sense of the term, the theory of reference is more or less co-extensive with the study of the semantics of singular terms, whereas, in the latter, broad sense, the business of the theory of reference is to assign semantic values to all independently meaningful expressions.

There also are differing views as to whether the term 'reference' just applies to language-world relations, or whether mental phenomena, such as concepts, also should be said to refer. On the one hand, some treat 'reference' as a two-place relation between a representation and what it represents, and so take the term to apply in kind to (at least) word-world and concept-world relations. In this inclusive sense, all thought or talk about something in particular involves reference to it. On the other hand, there are those who hold that there are important differences between referring to something and thinking of it, and so restrict to the term 'reference' to language-world relations. Their point is not so much to deny that the problems of word-reference and of concept-reference are intimately related – that is true on virtually any approach to the relation between language and thought. Rather, their point is that referring is something that speakers do in the course of performing speech acts, not something that words themselves do. These theorists hold that the fundamental notion in the theory of reference is *speaker's reference* – an irreducibly four-place relation involving a speaker, an expression, an audience, and a context.

For comprehensiveness, I will use the term 'reference' in a fairly broad, inclusive sense. For brevity, I will concentrate on uses of words, and I will treat reference as a two-place relation between a use of a word and its referent. Given these preliminaries and assumptions, the central problem for a theory of reference is to come up with a true, informative account of what the 'R' stands for in the schema:

[Ref] 'X' refers to Y if 'X' stands in relation R to Y

Descriptivism

Descriptivist Theories of Reference

Even though philosophical problems that turn on the notion of reference are more or less as old as

philosophy, the development of theories of reference – of explicit attempts to articulate how it is that terms reach out to their referents – does not occur until the seminal semantic work of Frege and Russell. (Some might argue that the idea theorists of the early Modern period had a theory of reference – see **Ideational Theories of Meaning** for discussion.) Down different avenues, Frege and Russell both defend descriptivist views about reference, and their views dominated the scene for most of the 20th century.

Descriptivists take the definite description ('the tallest woman in Mongolia', 'the millionth car to roll off this assembly line') as the paradigm for understanding the word-object referential link. The relation between descriptions and their referents is relatively straightforward: the term expresses an identifying condition, and designates whatever (if anything) uniquely satisfies that condition. In its most general sense, 'descriptivism' names the view that this is how reference works, that words refer to specific things by expressing an identifying condition which singles out the referent. For starters, then, let us characterize the core tenet of a descriptivist theory of reference as follows:

[D] 'X' refers to Y if Y satisfies the descriptive condition expressed by 'X'

There are more specific variants of descriptivism, which just apply to a distinctive category of terms, as opposed to making claims about reference in general. (For example, Lewis (1970) develops a descriptivist approach to theoretical terms.) The most common usage of 'descriptivism,' though, specifically designates an approach to ordinary proper names. According to this view, names such as 'Aristotle' or 'Romania' hook onto and express information about something in particular, akin to descriptions, by expressing a uniquely identifying condition and designating whatever satisfies the condition. This approach to ordinary proper names is the kernel in common among Frege's and Russell's otherwise rather divergent views about reference.

Frege's and Russell's Versions of Descriptivism

In their earliest work, Frege and Russell both espoused referentialist views of meaning, according to which the meaning of an expression is whatever it is to which the expression refers. However, they came to believe that referentialism must be rejected or modified, because two terms can have the same referent but differ in meaning.

Frege's signature example concerns the names 'Hesperus' and 'Phosphorus.' According to the lore, the Evening Star (the brightest heavenly body in the evening sky at certain times of the year) was baptized

‘Hesperus,’ whereas the Morning Star (the brightest body in the dawn sky at certain times) was baptized ‘Phosphorus’. With the growth of astronomical knowledge, it turns out that Hesperus *is* Phosphorus, and that is not a star at all but the planet Venus. Frege and Russell agree that pairs of sentences such as the following differ in meaning:

- 1a. Hesperus is Hesperus.
- 1b. Hesperus is Phosphorus.
- 2a. The ancient Babylonians believed that Hesperus is visible in the evening.
- 2b. The ancient Babylonians believed that Phosphorus is visible in the evening.

However, because these sentences are constructed from co-referential parts, the referentialist view is committed to treating them as synonymous.

Frege (1892) concludes that, in general, the meaning of a term is not just its referent. Instead, every significant linguistic expression is associated with a sense that determines its referent. The sense specifies the condition that must be met in order to be the referent, which clearly differ for the cases of ‘Hesperus’ and ‘Phosphorus.’ Co-referential expressions can have distinct senses, and expressions need not have an actual concrete referent to have a sense. Thus, on Frege’s view:

[D, Frege] ‘X’ refers to Y if Y satisfies the sense ‘X’ expresses

This type of view is called ‘mediated’ or ‘indirect’ reference. The link between word and referent is *indirect* because there is something *mediating* the word-referent link. On this approach, any referential relation involves three terms: [1] a sign or symbol, [2] its sense, and [3] the referent picked out by the sense. (Note that there may be no actual entity to serve as term [3] – as in the case of, say, ‘Santa Claus’ or ‘Pegasus.’ However, such cases still fit with the general picture, as the names express a sense that specifies the condition that must be met to count as the referent.) (see **Sense and Reference: Philosophical Aspects** for more on Frege’s view.)

Russell rejects Frege’s views, arguing that the postulation of intermediaries between word and referent creates rather than solves problems. Russell’s view is premised on a firm distinction between the following two sorts of term: “(1) a *name*, which is a simple symbol, directly designating an individual which is its meaning, and having this meaning ... independently of all other words; (2) a *description*, which consists of several words, whose meanings are already fixed, and from which results whatever is to be taken as the ‘meaning’ of the description” (1919: 283). (Following Russell [1918], I’ll call the former

‘logically proper names.’) Concerning logically proper names, Russell is a direct reference theorist, an unrepentant referentialist. Reference is *direct* in that there is no third term mediating the word-referent relation. The meaning of a logically proper name is its referent.

However, for the reasons illustrated by (1a–b) and (2a–b) above, Russell argues that ordinary proper names (such as ‘Hesperus’ or ‘Aristotle’) belong in the category of descriptions, not of logically proper names. He holds that it is not possible for co-referential logically proper names to differ in meaning – “For the name itself is merely a means of pointing to the thing ... so that if one thing has two names, you make exactly the same assertion whichever of the two names you use ...” (1918: 245). In contrast, descriptions (such as ‘the inventor of bifocals’ and ‘the first Postmaster General of the US’) can differ in meaning while describing the same referent. Russell concludes that, since ordinary proper names are subject to the phenomena illustrated by (1a–b) and (2a–b), they are really just disguised or abbreviated descriptions – “Common words, even proper names, are usually really descriptions” (1911: 253). Thus, Russell also espouses a form of descriptivism:

[D, Russell] For any ordinary proper name ‘N’, ‘N’ refers to Y if Y satisfies the description ‘the F’ which the speaker has in mind in uttering ‘N’

Differences Between Descriptivist Views

Despite the fact that Frege and Russell both espouse descriptivist accounts of ordinary names, their approaches to reference are quite far apart. On Russell’s direct reference view, there must be some primitive cases in which it is impossible to have sameness of referent but distinctness of meaning. He holds that we must be directly acquainted, and not just indirectly linked via descriptions, with the referents of some of our terms. (Otherwise “... we get the conclusion that we know nothing at all about ...” the referents of our terms, as Russell puts the point in a letter to Frege [reprinted in Frege (1980: 169)].) So, apart from, and more fundamental than, his views about ordinary names, Russell espouses an acquaintance-based theory of reference:

[A] ‘X’ refers to Y if Y is the entity with which the speaker is acquainted that the speaker intends to single out by uttering ‘X’

(It is crucial to Russell’s view that acquaintance is *immediate*, in that for any co-referential pair ‘X’-‘X*’, one cannot be acquainted with their referent and yet judge that X is distinct from X*.) Russell holds that one can only use a logically proper name

to refer to something to which one is directly acquainted (1918: 201). Furthermore, even in the case of a description, one can only understand a description if one is acquainted with the meanings of the terms of which it is composed (1911: *passim*) – i.e., to understand the term ‘the tallest woman in the room’, one must be acquainted with the meanings of ‘tallest,’ ‘woman,’ ‘room,’ and so on.

According to Russell, one needs to fall back on something like [A] in order to address questions that are subsequent to, and more fundamental than, a commitment to some version of [D]. In effect, [D, Russell] reduces the ordinary-naming-relation to the description-relation; but still, according to Russell, we do not yet have a theory of reference. In order to explain how ‘the tallest woman in the room’ expresses the specific identifying condition that it does, one needs an account of the referents of its primitive parts – i.e., a theory of reference for ‘tallest,’ ‘woman,’ and so on. Furthermore, this account had better not just appeal to more descriptions, or else we are not getting anywhere. So, Russell holds that [D] needs to be supplemented, if we are to have an account of how our utterances get hooked up to particular referents.

This problem never seems to have bothered Frege; and yet it is not clear whether this is an oversight. (Perhaps Frege’s senses are relevantly different from Russell’s descriptions; perhaps the moral is that a direct-reference-descriptivism needs to be supplemented by something like [A], whereas an indirect-reference-descriptivism does not.) In any case, it can be argued that [D] is not yet a theory of reference, because it presupposes, rather than explains or grounds, reference. To help oneself to some specific Y as that which satisfies the descriptive condition expressed by ‘X,’ so this Russellian allegation goes, is to beg the very question that a theory of reference ought to answer.

No such worry applies to [A]. Acquaintance is a clear and distinct answer to the fundamental question of reference. However, it puts rather tight constraints on reference. By 1918, Russell’s insistence that one must be immediately acquainted with something in order to refer to it lead him to the view that only ‘this,’ used to refer to current sense impressions, qualifies as a referring expression. Subsequent theorists have found this unacceptable, and so reject Russell’s tight restrictions on reference.

For decades, work in the theory of reference consisted largely of the development of other variants of descriptivism (cf. Searle [1958]; Strawson [1959]). However, some deep criticisms of descriptivism emerged in the 1970s, which lead to another major wave of original work in the theory of reference.

Antidescriptivism and the Causal-Historical Theory of Reference

Problems With Descriptivism

Kripke (1972) is the most thorough and influential critic of descriptivism, whereas Donnellan (1970), Putnam (1975), and Kaplan (1977) also develop important criticisms. Three widely discussed problems with descriptivist theories of names are known as the modal problem, the epistemic problem, and the semantic problem.

To illustrate the modal problem, take any proper name (say, ‘Aristotle’) along with descriptions that are true of its referent (‘the most famous of Plato’s students,’ or ‘the teacher of Alexander’). Consider the differences in truth-conditions of the following:

1. Aristotle had brown hair.
2. The most famous of Plato’s students had brown hair.

Even if (1)–(2) actually agree in truth-value, they need not have. Had things gone differently (and, say, Aristotle died young, or went into commerce), then the truth-values of (1)–(2) could vary independently – i.e., each might have been true while the other is false. A similar contrast could be drawn using virtually any name-description pair, and many take this phenomenon to indicate a deep difference between names and descriptions.

To illustrate the epistemic problem, if ‘Aristotle’ meant something like ‘Plato’s most famous student,’ then the following would be self-evident to anyone who understands it:

3. Aristotle is Plato’s most famous student.

This consequence is false, as (3) is not at all trivial or self-evident. Again the point generalizes, having nothing to do with this specific example; and the putative upshot is that names like ‘Aristotle’ are not equivalent in meaning to any particular descriptions.

The semantic problem is that speakers may be competent to use a name even if the descriptive conditions they associate with the name does not suffice to single out the referent. That is, one might just think that ‘Aristotle’ names some famous Greek guy (or perhaps even confuse Aristotle with Heraclitus), but yet nonetheless one could still refer to Aristotle by uttering ‘Aristotle’. Again, the conclusion seems to be that there are important differences between reference by name and the satisfaction of descriptive conditions. (*see Proper Names: Philosophical Aspects for discussion.*)

Collectively, these three problems are widely thought to spell the end for descriptivist accounts of names. (This is not unanimous, however – cf. Searle

[1983] and Bach [1987] for descriptivist replies.) Kripke (1972) and Putnam (1975) develop similar problems for some varieties of general terms. Still other, related problems for descriptivism are raised by indexicals – even if satisfactory descriptivist accounts could be given for some terms, it is not plausible to hold that all reference is descriptive, as is shown by cases like ‘It is quiet here now’ (cf. Kaplan [1977]).

The Causal-Historical Theory of Reference

The critics of descriptivism put forth a different picture of reference, known as the causal-historical theory. Originally, the theory is only developed for proper names (cf. Donnellan [1970]; Kripke [1972]) and natural kind terms (cf. Kripke [1972]; Putnam [1975]). However, there have been attempts to fashion more general, comprehensive views of reference along these lines (for discussion, see Stalnaker [1997]; Devitt and Sterenly [1999]).

The crux of this picture is that certain expressions refer to certain things in virtue of a causal-historical relation between word and object, initially fixed during a dubbing or baptism and propagated from there to subsequent speakers, who implicitly defer to that initial dubbing in using the expression to refer. The view has it that descriptivists are wrong to demand that, in order to significantly use a term, speakers are required to have an identifying description of its referent. Rather, once a word-referent convention is in place, all that is required in order to use the term to refer is a deferential intention to comply with the convention – i.e., the (implicit) intention to use ‘X’ to refer to what others have used ‘X’ to refer to. On this approach, reference depends not simply on what the speaker thinks, but also on certain factors external to the speaker’s head, factors pertaining to the speaker’s linguistic community and to the environment in which the expression in question evolved. The basic idea is:

[CHT] ‘X’ refers to Y if ‘X’ stands in the right sort of causal-historical relation to Y

(see **Causal Theories of Reference and Meaning** for more detail).

Many of Russell’s successors have worked to loosen the tight restrictions on his notion of reference, by replacing acquaintance with something more broadly applicable and accessible. The [CHT] is a significant step forward in this direction. It is an externalist theory of reference. Internalist views of reference hold that reference is fully determined by the intrinsic content of the speaker’s head; externalists deny this. Externalists hold that two speakers could be in the same mental state and utter the same

sounds, but nonetheless their utterances have different referents – because of differences in the histories of how the words reached them, or of differences in the environments to which they are causally connected. (For discussion, see **Externalism about Content**.)

Intuitively, reference is a relation involving (at least) a speaker, an expression, and a referent; externalists hold that it is a mistake to think that the nature of this relation could be fully characterized by analyzing only one term of this relation (i.e., the intrinsic content of the speaker’s head). Most theorists who articulated views about reference prior to the [CHT] (including Frege and Russell) are commonly characterized as internalists. In the wake of the [CHT], though, externalism about reference has become the norm. Most subsequent theorists agree that the [CHT] makes a progressive step forward, in giving some of the weight in determining reference to the extrinsic relations in which speakers stand to other speakers and to their environments.

The [CHT] led to a resurgence of interest in the notion of direct reference. Many take the arguments against descriptivism to apply to all indirect reference theories, and so to make it plausible that the meaning of a term is just its referent. In addition, many see a complementary fit between the causal-historical chain of transmission story about reference and the direct reference approach to the question of meaning or content. (see **Proper Names: Philosophical Aspects** for discussion.)

Problems With the Causal-Historical Theory

There are many problems with the causal-historical theory of reference. For instance, Evans (1973) points out that some words have in fact changed their referents over time, even despite the deferential intention to preserve the convention in question, and argues that the [CHT] cannot account for this phenomenon. For another example, Searle (1983: 249) offers as a *reductio* of the theory the putative consequence that his utterances of ‘Aristotle’ might refer to a barstool in Hoboken “if that is what the causal chain happened to lead to.” To cope with these and other problems, many have sought to defend hybrid views, which aim to combine the strengths while avoiding the weaknesses of [D] and [CHT] (cf. Evans [1973, 1982]).

More generally, though, the [CHT] leaves important questions unaddressed. One problem concerns specifying exactly what should count as ‘the right sort of causal-historical relation’. As Stalnaker (1997: 543) puts it: “Causal connections are ubiquitous ... there are a great many individuals causally

implicated in [any] use of [any] name. . . . A proper causal theory of reference would have to specify just what sort of causal connection is necessary and sufficient for reference, and that is a notoriously difficult demand.” Kripke (1972: 96) is explicit that he is not offering a reductive analysis of reference: “When the name is ‘passed from link to link’, the receiver of the name must, I think, intend to use it with the same reference as the man from whom he heard it, . . . [T]he preceding account hardly *eliminates* the notion of reference; on the contrary, it takes the notion of intending to use the same reference as a given.” (Cf. Kaplan’s [1990] discussion of the point that the intention to preserve reference is not itself a causal notion.) Here we see why the [CHT] is open to the allegation that it begs the key question in the theory of reference, by helping itself to successful reference. Critics allege that it boils down to the relatively toothless claim that: ‘X’ refers to Y if everyone else has used ‘X’ to refer to Y.

Of course, the [CHT]’s developers recognize the need for a separate story about what determines reference in the first link in a causal-historical chain of transmission. However, their remarks about baptisms or dubbings fall far short of a comprehensive account. (Cf. Devitt and Sterenly’s [1999] discussions of the ‘qua’-problem for a sense of some of the relevant unfinished business.) So, while most agree that the [CHT] provides a better picture than [D], it has yet to be fleshed out into a specific, comprehensive theory of reference.

Skepticism, Naturalism, and Minimalism About Reference

Some influential thinkers are skeptical about the prospects of coming up with a satisfactory theory of reference. Chomsky (1993), for instance, argues that the debates about reference are hopelessly flawed because they presuppose an implausible, unscientific conception of language. The precise import of Chomsky’s complaints is unclear, though. In particular, and explicitly, they do not apply to the relatively concrete and tractable notion of speaker’s reference (i.e., a four-place relation between speaker, expression, audience, and context).

Quine (1960) is perhaps the most influential skeptic about reference, arguing that there are no determinate facts about reference, no objective thing to be gotten right. Quine takes this conclusion (which he calls the ‘inscrutability of reference’) to be an instance of the general point that theories are underdetermined by evidence – i.e., for any finite set of data, there are an infinite number of distinct theories that are consistent with, and could purport to explain, the data.

In the case of reference, the claim is that, for any finite set of evidence about a given speaker, there are a number of distinct word-referent assignments that are compatible with it. (To take one of Quine’s central examples, no data will tell us whether a given speaker is using ‘rabbit’ to refer to rabbits, to time-slices of rabbits, to undetached rabbit parts, and so on.) There is no principled way of deciding between these competing assignments; and hence, there is no determinate fact of the matter as to what words are used to refer to. From here, Quine draws pessimistic conclusions about the scientific credentials of such notions as reference.

Many aspects of Quine’s approach have been criticized. Still, much subsequent work on reference is addressed to Quine’s underlying challenge of explaining reference within the ontology and methodology of the natural sciences. This is known as the demand for a naturalistic theory of reference, and a number of candidates were proposed in recent decades.

One such candidate is another causal theory of reference – also called the ‘information-theoretic’ approach (cf. Stampe [1977]; Dretske [1981]; Fodor [1990]). The general idea is that information is a species causal co-variance, that for a word ‘X’ to mean something Y is for tokens of ‘X’ to reliably indicate Y. As applied to reference, the view comes to something like:

[CT] ‘X’ refers to Y if Y tends to cause or bring about tokens of ‘X’

However, in addition to inheriting some of the general worries about [CHT], [CT] is subject to counterexamples. For almost any word-referent pair ‘X’–Y, it is not difficult to find conditions in which things distinct from Y tend to cause ‘X’s, and conditions in which Y does not tend to cause ‘X’s. Despite ingenious work to patch things up, the consensus seems to be that this type of causal theory can only succeed in delivering an account of reference that accommodates our intuitions about the normativity and determinacy of reference by smuggling in intentional, semantic notions, and thus by helping itself to reference and forgoing naturalism. (For discussion see Loewer (1997), and **Causal Theories of Reference and Meaning.**)

Another naturalistic approach to reference is the teleological theory, whose most thorough proponent is Millikan (1984). The idea here is that:

[T] ‘X’ refers to Y if it is the function of ‘X’s to indicate Y

Here ‘function’ is a familiar notion from evolutionary biology – roughly, X’s function is what X does, that explains why X exists. However, this theory, too,

has serious troubles accounting for the normativity and determinacy of reference (cf. Fodor [1990]; Loewer [1997]). Although teleological considerations afford a compelling story about why agents like us have developed the capacity to refer, it is a long way from there to specifying necessary or sufficient conditions for determining the referent of a given use of a word.

Another reaction to this long and sordid history is the minimalist (or ‘deflationary’) approach (cf. Horwich [1998]; Field [2001]). Minimalists hold that reference is simple, not reducible to anything more fundamental. (Minimalism about reference is often conjoined with minimalism about truth – see **Truth: Theories of in Philosophy** for discussion.) Our meaning what we do by ‘refers’ consists entirely in our inclination to accept disquotational schemas – ‘Aristotle’ refers to Aristotle, ‘Romania’ refers to Romania, and so on – and there is nothing else to be said, by way of necessary or sufficient conditions. Rather, all that should be said is something like:

[M] ‘X’ refers to X

[M] is of course no definition: reference is not reduced to, or explained in terms of, anything more basic. However, one conclusion that is fairly well supported by the failed attempts to define reference is that such a reductive analysis may well be unattainable. To some extent, it is a matter of taste whether one classifies minimalist views as theories of reference or as a variety of skepticism about reference.

Even if there is something right about the minimalist approach, though, [M] hardly seems to illuminate the content of the concept ‘reference.’ Furthermore, there are specific objections to minimalism (cf. Loar [1995]; Loewer [forthcoming]). For example, it is not clear that there could be a satisfactory minimalist account of indexical expressions. (That is, the disquotational line on ‘Aristotle’ and ‘Romania’ does not carry over smoothly to ‘I’ or ‘here.’) Because these are core, basic cases of reference, this might point to something deeply suspect about minimalist views.

Summary

The fundamental problem in the theory of reference (given our preliminary assumptions) is to come up with a true, informative account of what the ‘R’ stands for in the schema:

[Ref] ‘X’ refers to Y if ‘X’ stands in relation R to Y

Work in the theory of reference largely consists of disputes between two camps, descriptivists and causal-historical theorists:

[D] ‘X’ refers to Y if Y satisfies the descriptive condition expressed by ‘X’

[CHT] ‘X’ refers to Y if ‘X’ stands in the right sort of causal-historical relation to Y

Descriptivists tend to be internalists, and descriptive reference is mediated or indirect, whereas the causal-historical theory is externalist and more friendly to direct reference. As we have seen, though, whereas [D] and [CHT] are major players in the semantics of proper names, both are – albeit from different directions – open to the allegation that they presuppose rather than explain or ground reference.

Bracketing off reference via descriptive conditions and reference via deference to causal-historical chains (as well as the hybrid views), there are at least four other basic answers to the fundamental question of reference (respectively, acquaintance, causation, teleology, and minimalism):

[A] ‘X’ refers to Y if Y is the entity with which the speaker is acquainted that the speaker intends to single out by uttering ‘X’

[CT] ‘X’ refers to Y if Y tends to cause or bring about tokens of ‘X’

[T] ‘X’ refers to Y if it is the function of ‘X’s to indicate Y

[M] ‘X’ refers to X

The problem with Russell’s version of [A] is that it is incompatible with the platitude that reference is a tool used in the intersubjective communication of information – i.e., acquaintance is a private subjective affair, but reference is not. However, there is a recent resurgence of interest in the notion of acquaintance, and it promises to avoid some of these problems. [CT] and [T] have certainly not been ruled out, but counterexamples have yet to be satisfactorily addressed. (Note that it is indicative that there are two causal theories on this short-list – most philosophers concede that causal relations between speakers and their environments have to play a fundamental role in a satisfactory theory of reference.) Proponents of [M] also have some specific problems to account for, over and above its general tendency to elicit the atavistic impulse that the question of reference has not really been addressed.

Much philosophical work continues on these problems, and these debates are not in danger of conclusive resolution any time soon.

Referential versus Attributive

Donnellan's Contrast

Consider two utterances of the same sentence, S:

S: Smith's murderer is insane.

The first utterance, U(S)_{ATT}, is prompted by the speaker's discovery of Smith's savagely mutilated corpse roasting on a spit, with no culprit in evidence. The second, U(S)_{REF}, is prompted by an observation years later of a defendant, Jones, seen cross-eyed and frothing at the mouth as he climbs into the dock on trial for Smith's murder. As it happens, the real killer, Robinson, goes free and is perfectly sane (his crime

notwithstanding) while Jones, though falsely charged, is as mad as he looks. Many find it natural to suppose that the speaker of U(S)_{ATT} has said nothing correct about anyone while the speaker of U(S)_{REF} has said something correct about Jones, even if perhaps she has used the wrong words to do so. This is an example of the contrast between what Keith Donnellan labels – misleadingly on some views – attributive and referential uses of definite descriptions. Here is Donnellan's own characterization of the contrast:

A speaker who uses a definite description attributively in an assertion states something about whoever or whatever is the so-and-so. A speaker who uses a definite description referentially in an assertion ... uses the description to enable his audience to pick out whom or what he is talking about and states something about that person or

thing [T]he definite description is merely one tool for doing a certain job – calling attention to a person or thing – and in general any other device for doing the same job, another description or a name, would do as well. In the attributive use, the attribute of being the so-and-so is all important, which it is not in the referential use (Donnellan, 1966a: 285).

Attempts to account for how the contrast arises lie at the heart of work on the nature of the semantics/pragmatics boundary. This entry looks at the origins of Donnellan's distinction in his criticism of Russell's theory of descriptions, and then considers two approaches to the contrast, one that treats it as pragmatic in origin and the other that treats it as a genuinely semantic distinction.

Donnellan's Use of the Contrast against Russell

Donnellan introduced the distinction with a view to undermining Russell's theory of definite descriptions (Russell, 1905, 1919). Russell argued that the surface form of (1) below is misleading. It has an underlying logical form that, when interpreted, delivers the truth condition set out in (2):

- (1) 'The fish jumped'
- (2) An utterance of the sentence in (1) is true if and only if $\exists x ((x \text{ is a fish} \ \& \ \forall y (y \text{ is a fish} \rightarrow x = y)) \ \& \ x \text{ jumped})$

Definite descriptions, in other words, are non-namelike: nothing in the underlying logical form of sentences containing them corresponds to an object referred to by 'The fish.' (Russell also held that ordinary names are non-namelike in this respect too, but that is another matter.) By denying that the semantic function of definite descriptions is to pick out a single object in order then to say something about it, Russell hoped to solve a variety of puzzles. For example, it became possible to explain how a definite description can be used meaningfully even when less than one (as in (3)–(4)) or more than one (as in (5)) contextually salient object satisfies the description; or how identity statements made using definite descriptions can be informative as in (6) when an equivalent name would not be (as in (7)).

- (3) 'The king of France is bald': false but meaningful.
- (4) 'The king of France does not exist': meaningful and true.
- (5) 'The woman in the magician's box has been sawn in half': false but meaningful.
- (6) 'The author of the Waverley novels is Walter Scott': true and informative.
- (7) 'Walter Scott is Walter Scott': true but uninformative.

From Russell's perspective, these cases are puzzling only if one assumes that the entire semantic function of a phrase of the form 'the ...' is to single out an object that uniquely satisfies the property expressed by '...', in order then to say something about it with the rest of the sentence. If truth conditions are instead assigned along the pattern in (2), these examples cease to be troublesome.

According to Donnellan (1966a), Russell's theory copes adequately with $U(S)_{ATT}$ but not with $U(S)_{REF}$. It assigns the same truth conditions to both utterances:

An utterance of *S* is true if, and only if, $\exists x ((x \text{ murdered Smith} \ \& \ \forall y (y \text{ murdered Smith} \rightarrow x = y)) \ \& \ x \text{ is insane})$

Intuitively, $U(S)_{REF}$ would need to be withdrawn if Jones were in fact sane, while $U(S)_{ATT}$ would not be affected; and Robinson's mental health is irrelevant to $U(S)_{REF}$ despite being highly relevant to $U(S)_{ATT}$. Donnellan took these intuitions, and others elicited by similar cases (e.g. 'Who is the man drinking a martini?' asked of someone who is in fact drinking water) to refute Russell's theory, at least in so far as the latter was intended to give a comprehensive account of definite descriptions.

It is unclear whether Donnellan thought his distinction had a pragmatic or a semantic origin. The fact that he takes it to refute Russell suggests he took it to be semantic. Russell's theory was, after all, a theory of the semantics of definite descriptions, not of their pragmatics. But he persistently talks of *uses* of definite descriptions, and at one point even writes explicitly that

[...the] grammatical structure of the sentence seems to me to be the same whether the description is used referentially or attributively: that is, it is not syntactically ambiguous. Nor does it seem at all attractive to suppose an ambiguity in the meaning of the words; it does not appear to be semantically ambiguous. (Perhaps we could say that the sentence is pragmatically ambiguous: the distinction between roles that the description plays is a function of the speaker's intentions.) (Donnellan, 1966a: 297)

It is possible that Donnellan's position, further developed in Donnellan (1968), is just that no pragmatic theory is available to complement Russell's semantic theory in such a way as to explain referential uses as well as attributive ones. In that case, even if there is no semantic ambiguity, Russell's semantic theory would have to be rejected. But a more likely explanation of the contrary indicators in his paper is the primitive understanding of the semantics/pragmatics boundary at the time.

Whatever we take Donnellan's own view to be, most reactions to his contrast can be classified

according to whether they treat the difference as semantic or as pragmatic. Some treat his contrast as a difference in use alone, while others claim the difference in use is a symptom of a genuinely semantic ambiguity. Pragmatic approaches are now slightly more popular, but the only genuinely uncontroversial claim to be made in this area is that reflection on Donnellan's contrast has forced everyone to be clearer than they were about what the semantics/pragmatics distinction actually is (see **Semantics–Pragmatics Boundary**). In what follows I will outline two paradigmatic treatments, one from each camp.

Pragmatic Treatments (Kripke)

Kripke's role as a critic of Russell's theory of reference is well known (Kripke, 1980), so it might seem surprising that in this context he is Russell's defender. The explanation is simple: Russell's theory of descriptions has two components. On the one hand, and as detailed above, he claimed that definite descriptions have a complex logical form that is not easily read off from their surface structure. But he also claimed that ordinary names are in fact disguised definite descriptions (**Figure 1**). After all, the same puzzles that his theory of the logical form of descriptions is supposed to solve arise equally for ordinary names, so this is a natural extension. In *Naming and necessity*, Kripke rejects the claim that ordinary names are covert definite descriptions but leaves Russell's treatment of definite descriptions as such largely unchallenged. In Kripke (1977) he defends Russell, against Donnellan's criticism at least.

Kripke's response to Donnellan is methodologically elegant (1977: 3c). He imagines a population that has a language like English but, stipulatively, it has a Russellian semantics for definite descriptions. He then asks whether the contrast between referential

and attributive uses of definite descriptions would arise in such a population. It would, he argues. Indeed, Kripke suggests, if speakers of this language did not use 'The F is G' at all, but instead used 'there is an F, identical with anything that is F, and it is G,' an analogue of Donnellan's distinction would still arise. They would use this sentence when they wished to attribute G-ness to something they, mistakenly, believed to be the unique possessor of F-ness. Kripke infers from this that existence of Donnellan's contrast *among speakers of English* does not undermine the claim that English definite descriptions have the semantics Russell says they do.

Kripke's position can be explicated using a famous example due to Paul Grice (1975: 33). A letter of reference for an academic position contains the following evaluation of a weak candidate:

Mr X's command of English is excellent, and his attendance at tutorials has been regular. Yours, etc.

The referee is damning the candidate with faint praise. But in other contexts the sentence could be used without any negative insinuation. This possibility hardly shows that the sentence itself is semantically ambiguous, having a faint-praise sense and a neutral sense. Likewise, Donnellan's contrast does not, according to Kripke, show that S itself is semantically ambiguous. (Grice's own views on Russell's theory are in his 1989 title; see also Neale, 1990: 78; section 3.5.)

The challenge with all pragmatic theories is to provide more than a hand-waving demonstration of how the relevant phenomenon arises systematically from a feature of the conversational context rather than a feature of syntax. Kripke's derivation is based on a distinction he introduces between speaker's referent and semantic referent, which is itself a special case of Grice's distinction between what a speaker means 'on an occasion,' a matter of their intention, and what the expression means 'timelessly.' Roughly, the identity of the semantic referent for a particular use of a referring expression is governed by the conventional rules of the speaker's language or idiolect. These semantic rules establish a condition that something must meet in order to be the referent of the expression whenever it is used. The speaker's referent is what she wishes to talk about and which, so she will typically believe, meets the conditions for being the semantic referent of the expression she therefore uses in an effort to satisfy this wish. Much of the time semantic referent and speaker's referent will be the same entity. But if for example the speaker is mistaken in believing, of the object she wishes to talk about, that it meets the condition for being the semantic referent of the expression she uses, then the two can be distinct.

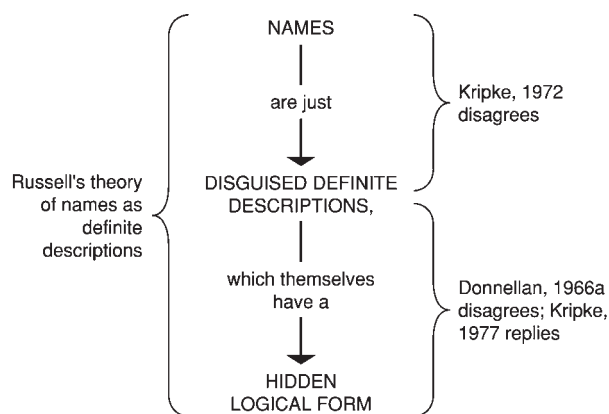

Figure 1 Russell's theory of names as definite descriptions.

Using this distinction, Kripke explains how Donnellan's phenomenon would arise in a language stipulated to assign Russellian truth conditions to definite descriptions. The contrast would emerge out of a distinction between two kinds of wishes its speakers could have when using a definite description. One kind of wish would be to talk about the semantic referent as such, no matter which object that should turn out to be. Another kind of wish would be to say something about a specific object, where use of the definite description would fix the audience's attention on that object whether or not the object is in fact the semantic referent. Kripke claims that this difference in wish would not affect the identity of the semantic referent.

These considerations do not show that English is a Russellian language, with 'the F is G' suffering from no lexical or structural ambiguity. They are compatible with its being the case that some utterances of this sentence are true just in case there is a unique F and it is G, while others are true just in case *an entity the speaker has in mind is uniquely F* is G. But in the absence of independent evidence, Kripke thinks the default assumption should be the simpler one: definite descriptions have a unitary, Russellian semantics. In support of this claim that the no-ambiguity position should be the default, he notes that there is something slightly awkward about describing $U(S)_{REF}$ as true ... about describing the utterance of $U(S)_{REF}$ as strictly true, even if it manages somehow to convey a true proposition.

Semantic Treatments (Wettstein)

Kripke in effect throws down a challenge: show that the difference in use has semantic significance. Wettstein (1981) takes up that challenge. However, his understanding of the attributive/referential distinction differs importantly from Donnellan's. In Donnellan's original examples of referential use, the object referred to fails to be a unique satisfier (in the context) of the descriptive element of the definite description. If all examples were like this, and the existence of a semantic distinction depended on the intuition that such examples were true, the semantic ambiguity thesis would be in trouble. According to Wettstein, Donnellan could and should have illustrated the referential use using only examples in which the object the speaker intends to refer to is a unique satisfier (in the context) of the descriptive element of the definite description. So suppose now that Jones *is* guilty, and no one else is. Wettstein takes the distinction between $U(S)_{REF}$ and $U(S)_{ATT}$ to consist in a difference in the proposition the sentence semantically expresses on each occasion. The proposition expressed by sentences containing a definite

description can have either of two structures, he holds. In referential uses, the proposition is singular. That is, among its constituents, and corresponding to the definite description, is a single object – Jones, say. In attributive uses, the proposition has a general or quantificational structure so that Jones is not a constituent of the proposition. These two propositions are distinct even though the single object must be the unique satisfier of the description for the singular proposition to be true. So Wettstein sees no need to follow Donnellan (as he is often interpreted) in making the further claim that referential uses can be correct even if the referred to object is not the unique satisfier of the description. This further claim is far more tenuous (Kripke, 1977; Lockwood, 1975; Wiggins, 1975).

This clarification of the distinction undermines a widespread reason for denying there is any semantic ambiguity, but it does not show that there is one. Wettstein argues for the positive thesis by noting that referentially used descriptions express a determinately true or false proposition, despite being 'incomplete.' Thus it is possible to utter (8) truly despite there being more than one table in existence.

- (8) 'The table is covered in books'

How is determinacy achieved in the face of incompleteness? According to Wettstein, standard Russellian answers fail. A typical answer would be to say that the incomplete description is tacitly completed in some way. For example, 'table' in (8) is elliptical for (9).

- (9) 'table in the north-east corner of the kitchen at
36 Richmond Way in Harwich, England'

Wettstein responds that how the description is completed is itself indeterminate. It could equally have been (10).

- (10) 'table beside the kitchen window at
36 Richmond Way in Harwich, England'

The same table satisfies each description uniquely, but the descriptions are nonetheless distinct. So no general proposition is uniquely determined. The determinacy of incomplete referential uses *can* be explaining by supposing that definite descriptions function, like demonstratives, to pick out some contextually and conversationally salient table, Wettstein adds. But explaining the determinacy this way has too high a cost for Russellians: the proposition semantically expressed would need to be singular.

Developments

Not everyone has found this argument convincing (see Soames, 1986, Salmon, 1982, Wettstein, 1983, and Reimer, 1998, for discussion). But there are other kinds of argument in favour of interpreting the

contrast as semantic. In a different paper Donnellan himself argued for the ambiguity thesis by considering the behavior of descriptions inside modal operators:

Consider the ambiguity of the counterfactual sentence: "If the President were the author of 'On Denoting,' we would not be in Vietnam." This may be construed as a sentence about Johnson, but there is a second reading on which it is not about him. If it is construed as being about him, then the relevant identity statements give rise to legitimate substitutions; otherwise not. On either reading, the sentence as a whole is non-truth functional, because counterfactual. The ambiguity is not to be explained by supposing that 'the President' refers to Johnson in both cases but that in one case the sentence ascribes a property to him but on the other reading it does not. Rather, on one reading 'the President' does not refer to Johnson at all (Donnellan, 1966b: 687)

Important to the resolution of the issue is the observation, ignored here for brevity, that the referential/attributive contrast may apply to other expressions, including indefinite descriptions, demonstratives, and perhaps even pronouns and names. (For further arguments favouring the semantic position, see Devitt, 1981: 2.5–2.7, 1998, 2004, and Devitt and Sterelny, 1999.)

Relevance Theory

F Yus, University of Alicante, Alicante, Spain

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (henceforth RT), a cognitive theory of human communication developed by D. Sperber and D. Wilson, was fully described in their 1986 book (Sperber and Wilson, 1986, 2nd edn., 1995), but it really

emerged in the late 1970s and early 1980s as a cognition-centered alternative to Grice's cooperation-ruled explanation of human communication (see Wilson and Sperber, 1981). Since then, it has been a highly influential theory in pragmatics producing a good number of studies backing it up, criticizing it, or applying it to different pragmatic research areas (see Yus, 1998; Wilson and Sperber, 2002a; and RT Bibliography).

The main assumption of the theory is that human beings are endowed with a biologically rooted ability to maximize the relevance of incoming stimuli (including linguistic utterances and other communicative behavior). Relevance is not only a typical property of external stimuli (e.g., utterances), but also of internal representations and thoughts, all of which may become inputs for cognitive processing. The pursuit of relevance is a typical aspect of the mental activity of human beings, always geared to obtaining the highest reward from the stimuli that they process. This biological endowment is the result of the evolution of the architecture and complexity of the human mind and part of a general human ability to meta-represent one's and other people's thoughts and intentions: "As a result of constant selection pressure towards increasing efficiency, the human cognitive system has developed in such a way that our perceptual mechanisms tend automatically to pick out potentially relevant stimuli, our memory retrieval mechanisms tend automatically to activate potentially relevant assumptions, and our inferential mechanisms tend spontaneously to process them in the most productive way" (Wilson and Sperber, 2002a: 254). Together with another uniquely human cognitive endowment, the ability to metarepresent one's and other people's thoughts and intentions, this tendency to maximize relevance allows us to predict what information is likely to be relevant to other people and what interpretive steps might be involved in its processing, and therefore allows for the manipulation of other people's thoughts.

Basic Claims

Four statements can summarize this theory (Wilson, 1994: 44): (a) the decoded meaning of the sentence is compatible with a number of different interpretations in the same context; (b) these interpretations are graded in terms of accessibility; (c) hearers rely on a powerful criterion when selecting the most appropriate interpretation; and (d) this criterion makes it possible to select one interpretation among the range of possible interpretations, to the extent that when a first interpretation is considered a candidate matching the intended interpretation, the hearer will stop at this point.

These statements can be broken down into a number of basic claims, as summarized below.

Code versus Inference

Unlike the so-called **code model** of communication, according to which messages are simply coded and decoded, Sperber and Wilson favor an **inferential model** in which decoding plays a minor role compared with the inferential activity of the interpreter.

Within this approach, the decoding of utterances underdetermines their interpretation and serves rather as a piece of evidence about the speaker's meaning. Verbal communication does involve the use of a code (i.e., the grammar of the language), but inference plays a major role in turning the schematic coded input into fully propositional interpretations.

One of the most interesting contributions of RT is, precisely, the claim that there is a wide gap between the (coded) sentence meaning and the (inferred) speaker's meaning, which has to be filled inferentially. Comprehension starts at the context-free identification of the utterance's logical form, which is then enriched to yield explicit information (**explicatures**) and/or implicit information (**implicatures**) (*see Implicature*).

A Post-Gricean Theory

Sperber and Wilson acknowledge the filiation of RT from Grice's view of communication, but there are several aspects in which they depart from Grice. This is the reason why we can call RT a post-Gricean theory, a theory that takes the Gricean approach to communication as a mere starting point, as opposed to neo-Gricean theories which stay much closer to Grice's cooperative principle and its maxims (*see Cooperative Principle; Maxims and Flouting*). Several points deserve explanation:

1. One of the major contributions by Grice was to underline the role that intentions (roughly defined as mental representations of a desired state of affairs) play in human communication. His emphasis on the expression and recognition of intentions laid the foundations of the inferential model of communication. Crucially to Grice, the hearer explains the speaker's communicative behavior by identifying the underlying intention, a typically human form of mind-reading activity. However, Sperber and Wilson do not agree with the complex schema of human reasoning that Grice proposed for the derivation of implicatures.

Sperber and Wilson also point out that Grice's emphasis on the role of intentions corroborates the fact that communication can exist without the need for a code. All that the communicator has to do to communicate a thought is to get the addressee to recognize his/her intention to convey it.

Sperber and Wilson distinguish two levels of intention: **informative** (an intention to inform the hearer of something) and **communicative** (the intention to inform the addressee of that informative intention). In inferential communication, the identification of the informative intention is done through the identification of the communicative intention, the process being activated by verbal ostensive

communication, in which it is clear to both speaker and hearer (**mutually manifest** in Sperber and Wilson's terminology) that the speaker has the (metarepresentational) intention to communicate something. Unlike other forms of information transmission, 'ostensive inferential communication' involves both types of intention, and is achieved by ostensively providing an addressee with evidence that helps him/her infer the speaker's meaning.

2. RT explains the hearer's inference of the (intended) speaker's meaning from the coded sentence meaning by resorting to another central claim suggested by Grice: that ostensively communicated utterances automatically generate expectations that activate the hearer's search for the speaker's meaning. But whereas Grice explained these expectations in terms of the assumption by hearers that speakers were observing the cooperative principle and its maxims, within RT these expectations are explained in cognitive terms (basically proposing the existence of a Cognitive Principle of Relevance), without reliance on a cooperative principle.
3. For Sperber and Wilson, no maxims, in the Gricean sense, are required for the explanation of communication. This is especially evident in the case of the Maxim of Quality (roughly, 'tell the truth'), which Grice proposed for the explanation of figurative language and irony. Sperber and Wilson have shown that people are normally 'loose' when they speak and only on very specific occasions do they intend their utterances to be regarded as literally true. In addition, Sperber and Wilson propose that all uses of language, whether loose (metaphor, hyperbole, etc.) literal can be addressed with a single explanatory framework based on general expectations of relevance.

Two Principles of Relevance

Initially, Sperber and Wilson proposed one Principle of Relevance to account for the fact that an act of 'ostension' carries a guarantee of its eventual relevance, but in the Postface to the second edition of their book (Sperber and Wilson, 1995: 260ff.), they propose that we can distinguish a broad **cognitive principle of relevance**: "human cognition tends to be geared to the maximisation of relevance," as well as a narrower (**communicative principle of relevance**: "every act of ostensive communication communicates a presumption of its own optimal relevance"; 1986: 158), the latter being the main focus of analysis within pragmatics. But the former is important, too, because it stresses the fact that we are biologically geared toward processing the most relevant inputs available. In addition, it is this evolved disposition

that allows for the prediction of the mental states of others, which is crucial in human communication.

The communicative principle involves a definition of optimal relevance comprising two parts: (a) The ostensive stimulus is relevant enough for it to be worth the addressee's effort to process it; and (b) The ostensive stimulus is the most relevant one compatible with the communicator's abilities and preferences (Sperber and Wilson, 1995: 267, 270). As Wilson and Sperber (2002a: 257–258) correctly point out, communicators "cannot be expected to go against their own interests and preferences in producing an utterance. There may be relevant information that they are unable or unwilling to provide, and ostensive stimuli that would convey their intentions more economically, but that they are unwilling to produce, or unable to think of at the time." All this is covered by clause (b) of the definition of optimal relevance, which states that the ostensive stimulus is the most relevant one "that the communicator is **WILLING AND ABLE** to produce" (Sperber and Wilson, 1995: 258).

Assessing Relevance: Cognitive Effects versus Processing Effort

Unlike what is the case in 'static' pragmatics, which foregrounds the importance of context but somehow takes it for granted or is merely interested in dissecting, as it were, its elements, Sperber and Wilson's theory views the context as a dynamic, mental entity made up of a subset of the person's assumptions about the world; it is this subset that is accessed in the search for relevance. Often several extensions of context are required to arrive at an optimally relevant interpretation, but as soon as one interpretation is found to be satisfactory, interpretation stops and no other interpretive hypotheses are considered: "When a hearer following the path of least effort finds an interpretation which satisfies his expectations of relevance, in the absence of contrary evidence, this is the best possible interpretive hypothesis" (Wilson and Sperber, 2002b: 605).

The aforementioned Communicative Principle of Relevance predicts a basic procedure for hearers when hypothesizing about contextual extensions required for the interpretation of a verbal stimulus: to consider interpretive hypotheses in order of accessibility (following a path of least effort) and to stop when they arrive at an interpretation which satisfies the expectations of relevance raised by the stimulus itself. Relevance, then, is a matter of balance between the interest that the utterance might provide (in terms of so-called 'positive cognitive effects') and the mental effort that obtaining this interest demands.

Relevance is a characteristic of an input to the human cognitive processes which, when processed in a certain

context, yields positive cognitive effects. Because there are too many possible stimuli to which we can pay attention, our cognitive architecture is designed to allocate our processing effort in such a way that benefit is maximized. Hence, relevance has to do with the improvement of the person's knowledge; this can be achieved either by adding new information, by revising existing assumptions, or by yielding new conclusions resulting from the combination of old and new information (in this case **contextual implicatures** are generated).

The definition of relevance of an input to an individual involves two clauses: "(a) everything else being equal, the greater the positive cognitive effects achieved in an individual by processing an input at a given time, the greater the relevance of the input to that individual at that time; and (b) everything else being equal, the smaller the processing effort expended by the individual in achieving those effects, the greater the relevance of the input to that individual at that time" (Wilson and Sperber, 2002b: 602).

Current Issues and Open Debates

The Explicit/Implicit Distinction

One of the key differences between Grice's model and Sperber and Wilson's lies in the demarcation of explicit and implicit communication. For Grice, **what is said** involved little inference, mainly reduced to disambiguation and reference assignment, while all the inferential load was laid upon the derivation of implicatures, the latter being obtained **after** an interpretation reduced to the literal meaning has been found inappropriate, in a so-called **dual-stage processing**. Sperber and Wilson reject this view and favor a more adequate, **mutual parallel adjustment** of explicit content – explicatures – and implicit import – implicatures – during interpretation, and with no preconceived sequential arrangement.

Within RT, explicitly communicated information not only demands as much contextualization as do implicatures, but also covers aspects of communicated meaning which Grice included in the term implicature (e.g., the so-called **generalized conversational implicatures**, most of which are now pictured as explicit information, see Levinson, 2000; Carston, 2002).

In addition to implicatures, Sperber and Wilson propose two types of explicitly communicated information: the basic-level **explicature**, and the **higher-level explicature**. The latter also includes the speaker's attitude (*to regret that ... to be happy that ... etc.*) or a higher-order speech-act schema (*to be asking that ... to be ordering that ... etc.*). Both explicatures and implicatures allow for degrees (i.e., strong and weak

explicatures/implicatures), depending on the addressee's responsibility for their derivation and the amount of mental processing required.

Other notions used by other authors in the definition of explicit information, for instance **literal meaning** or **what is said**, are put into question by Sperber and Wilson, because these do not play any useful role in the study of verbal comprehension: "even when a literal meaning is available, it is not automatically the preferred interpretation of an utterance. In fact, literalness plays no role in our account of language comprehension, and nor does the notion of what is said" (Wilson and Sperber, 2002b: 586). This is because, among other reasons, hearers commonly derive loose interpretations rather than purely literal ones: "hearers have no objection to strictly false approximations as long as the conclusions they bother to derive from them are true. In fact, they might prefer the shorter approximations to their longer-winded but strictly true counterparts for reasons of economy of effort" (Wilson and Sperber, 2002b: 598).

Whereas Bach (1994) has proposed a third term, **implicature**, half-way between explicatures and implicatures, other authors, such as Vicente (2002), reject this blurring of the explicit/implicit dichotomy. The term 'implicature' covers several cases which would fit into Sperber and Wilson's notion of explicature, basically being completions of the semantic representation of the sentence (e.g., 'The table is too wide' [to go through the door]) and nonliteral uses of sentences in which no constituent is being used non-literally, what Bach calls **standardized nonliterality** (e.g., (said to a person who has cut himself) 'You are not going to die' [from this cut]).

Conceptual and Procedural Encoding

One of the most interesting lines of research within relevance theory is the one that differentiates between **conceptual meaning** and **procedural meaning**. Wilson and Sperber (1993: 10) summarize this dichotomy as follows: "inferential comprehension involves the construction and manipulation of conceptual representations; linguistic decoding feeds inferential comprehension; linguistic constructions might therefore be expected to encode two basic types of information: concepts or conceptual representations on the one hand, and procedures for manipulating them on the other."

Most words encode concepts, but some words give instructions as to how conceptual representations are to be manipulated and hence encode procedural meaning. Blakemore and her followers applied the notion to connectives (Blakemore, 1987) and discourse markers (Blakemore, 2002), which constrain the inferential phase by indicating the kind of

inferential process that the hearer should go through (hence reducing the eventual overall effort) in the subsequent stretch of discourse. In recent research, the list of procedural items has been extended to cover nonverbal elements such as intonation (*see Meaning: Procedural and Conceptual*).

***Ad hoc* Concept Formation**

The notion of *ad hoc* concept construction is one of the latest developments of relevance theory in the area of figurative language (especially metaphors), which has also been extended to the analysis of how concepts in general are processed (cf. Carston, 2002; Pilkington, 2000).

The traditional relevance-theoretic account of figurative language relies on the assumption that there is an interpretive resemblance between the coded concept and the intended thought. And we can say the same about the whole utterance whose propositional form resembles the propositional form of the communicator's thought (Pilkington, 2000: 90). From this viewpoint, the interpretive resemblance between, for instance, a coded metaphor and the thought which it resembles would lead to the hearer's derivation of stronger/weaker implicatures.

Within an alternative account of utterance interpretation, it is claimed that the metaphor provides a new *ad hoc* concept for the proposition expressed by the utterance (instead of favoring the derivation of implicatures) (*see Metaphor: Psychological Aspects*). Encyclopedic entries would be explored in such a way that an increase in the *salience* of a number of assumptions is created, providing an encyclopedic entry for the new concept (Pilkington, 2000: 95-96; for 'salience,' see Giora, 2002). They are *ad hoc* "because they are not linguistically given, but are constructed online in response to specific expectations of relevance raised in specific contexts. There is a difference then between *ad hoc* concepts, accessed by a spontaneous process of pragmatic inference, and lexicalized concepts, which are context-invariant" (Carston, 2002: 322).

Mutual Knowledge versus Mutual Manifestness

Sperber and Wilson reject the traditional notion of mutual knowledge because it generates an endless recursion (A knows that p, B knows that A knows that p, A knows that B knows that A knows that p, and so on). Instead, they propose the notion of **mutual manifestness** (*see Sperber and Wilson, 1990*). What is 'manifest' is what one is capable of inferring or capable of perceiving, even if one hasn't done so yet. The sum of all the manifest assumptions is the person's **cognitive environment**. A set of assumptions manifest to several individuals constitutes their

shared cognitive environment. When it is manifest to all the people sharing a cognitive environment that they share it, then, this is a **mutual cognitive environment**, made up of mutually manifest assumptions. Communication is a matter of making certain assumptions mutually manifest to both speaker and hearer.

Several authors have criticized the notion of mutual manifestness. For example, Mey and Talbot (1988) point out that what Sperber and Wilson do is to send mutual knowledge out at the front door and then let it in at the back, disguised as 'mutually manifest assumptions.' For these authors, cognitive environments are not distinguishable from mutual knowledge; thus, Sperber and Wilson appear to be using the same concept that they want to abandon. To my knowledge, neither Sperber and Wilson nor their critics have been persuaded to abandon their differing claims on mutuality.

Communicated and Noncommunicated Acts

One of the most underdeveloped areas within relevance-theoretic research is the relationship between RT and speech acts. In short, Sperber and Wilson (1986: 244-246) distinguish between communicated and noncommunicated acts. The former depend on the addressee's perception that a certain speech act has been performed (e.g., admitting, promising, thanking), while in non-communicated acts, communication does not depend on the identification of a particular speech act (e.g., predicting, warning, suggesting). In this case, successful communication lies in the hearer's recovery of adequate cognitive effects from the utterance with the aid of context and in the recovery of the speaker's intentions.

In a recent paper, Nicolle (2000) has argued against the existence of noncommunicated speech acts in the RT sense. Examples of noncommunicated acts (such as the act of warning in "The path is slippery here") are reconsidered by Nicolle in social terms, and their influence on the interlocutors' social environments implies that they also have to be communicated: "the recovery of information relating to social relations is an essential element of the comprehension process. When the recovery of such information depends on the identification of a particular speech act, that speech act is by definition a communicated act" (Nicolle, 2000: 239).

Irony and the Notion of Echo

In Wilson and Sperber (1992), the authors conceptualize irony in **interpretive** terms. An ironic utterance is an interpretation of another thought, utterance, or assumption that it resembles and which the speaker attributes to a different speaker or to himself/herself

at another time. Ironic utterances are echoic, that is, they simultaneously refer to an attributed thought – or utterance, or assumption – and express an attitude to it. More specifically, the speaker's attitude toward what is echoed has to be dissociative. This dissociation may apply to either the proposition expressed by the utterance, or to some effect that is generated by that utterance.

Several authors have commented upon this proposal. For instance, in some of the papers collected in Carston and Uchida (1998) it is claimed that irony can be nonechoic. In their reply, Sperber and Wilson (1998) maintain that although most utterances cannot be understood as echoic (i.e., there is no accessible representation that they might be taken to echo), an utterance has to be echoic to be interpreted as ironical (see *Irony*).

Modularity

Initially, Sperber and Wilson adopted the view of the mental architecture of the mind proposed by Jerry Fodor in the early 1980s: several modules feeding a central processor with specific information.

Modules are evolved, special-purpose mental mechanisms, typically automatic, informationally encapsulated, and domain-specific. For instance, the language module is only (and automatically) activated by verbal stimuli, feeding the central processor with a schematic logical form which then has to be enriched inferentially.

Over the last few years, this view of the mind has changed within RT (and also within evolutionary psychology), especially concerning the structure of the central processor, which is also regarded to be modular (Carston, 1997; Sperber and Wilson, 2002; Wilson, 2003). The most important module, specifically a submodule of the general 'theory of mind' ability, is **the pragmatic module**, which also exhibits qualities typically associated with modules. For example, this pragmatic module is biologically endowed, only activated by a specific type of information (ostensively communicated information), and constrained by its own principle: the Communicative Principle of Relevance.

Relevance Theory as Asocial

RT has been criticized for being hyperindividualistic and for avoiding the social aspects of communication (Mey and Talbot, 1988). Sperber and Wilson (1997: 147) acknowledge that they have concentrated on the inferential activity of the individual, but inferential communication is **also** essentially social: "Inferential communication is intrinsically social, not just because it is a form of interaction, but also, less trivially, because it exploits and enlarges the scope of basic

forms of social cognition. Right or wrong, this is a strong sociological claim." Although Sperber and Wilson have not studied uses of communication to convey information about the social relationship between the interlocutors, they do not mean to deny its importance, or to express a lack of interest in the issues or the work done; they merely feel that, at this stage, they can best contribute to the study of human communication by taking it at its most elementary level, and abstracting away from these more complex (socially connoted) aspects (Sperber and Wilson, 1997). Hence, for them, although "so far, the contribution of relevance theory to the study of human communication has been at a fairly abstract level... it seems to us to have potential implications at a more concrete sociolinguistic level" (Sperber and Wilson, 1997: 148).

A proposal by Escandell-Vidal (2004) aims at integrating inferential and social issues in terms of principles and norms, respectively, and as part of a domain-specific picture of mental activity. The mind operates according to principles that are in charge of obtaining fully propositional interpretations from coded stimuli. When dealing with norms, the mind is engaged in both a long-term and a short-term task. The short-term one analyzes and categorizes incoming information, and the long-term task builds up and updates socially accepted behavior.

Empirical Evidence

A common criticism of RT is that it is highly speculative, predicting without empirical evidence the mental procedures and interpretive steps the human mind goes through in human communication. Obviously, we are dealing with an object of study, the human mind, which is highly complex and still largely unexplained.

Sperber and Wilson (2002: 143) acknowledge that in much pragmatic research, there is a certain reluctance to get down to experimentation. However, relevance theorists have been particularly eager to combine theoretical issues with all the possibilities of testing provided by the careful use of linguistic intuitions, observational data, and the experimental methods of cognitive psychology (see Wilson and Sperber, 2002b: 607, note 7 for references). Recent research has aimed at an empirical explanation of central claims of the theory. For instance, Van der Henst and Sperber (2004) review various experimental tests of the two Principles of Relevance. They claim that the hypothesis that hearers spontaneously rely on a relevance-guided interpretive procedure can be experimentally tested either by intentionally manipulating the effort required to process a stimulus

or by changing the order of accessibility of several competing interpretations for the same stimulus. Another possible test is a manipulation of the effect factor by making a specific interpretation more or less likely to satisfy the expectations of relevance.

Other studies have focused on other possible areas of RT-based empirical research. Among them we can underline the ones on the Wason selection task. For example, Sperber *et al.* (1995) tested how participants derive implications from conditional statements in order of accessibility, stop when their search for relevance reaches an adequate balance of cognitive effects and processing effort, and select cards on the basis of this interpretation. The authors were able to manipulate the effort and effect factors by varying the content and context of the conditional statement, so as to elicit correct or incorrect selections at will (cf. Wilson and Sperber, 2002a: 279).

The plausibility of a Gricean maxim of truthfulness to explain human communication has also been tested (Van der Henst *et al.*, 2002). These authors showed that when people ask a stranger the time in the street they get, as a reply, “a time that is either accurate to the minute or rounded to the nearest multiple of five, depending on how useful in the circumstances they think a more accurate answer would be” (Wilson and Sperber, 2002b: 598), regardless of whether the people asked have (accurate) digital watches. These rounded answers are not strictly true, but they are easier for their audience to process.

Applications

RT has been applied to a number of research areas, among which we can distinguish the following.

1. **Grammar.** For RT the interest lies in how grammatical attributes constrain the choice of a candidate interpretation. In this sense, the grammatical arrangement of utterances plays an important part throughout this cognitive contextualization. From this point of view, several aspects of grammar have been addressed, including connectives (often within a conceptual/procedural account), conditionals, modals and modality, adverbs and adverbials, mood(s), tense(s), the article, etc.
2. **Humor.** Within a relevance-theoretic approach, humor is no longer a property of texts and, instead, what we need to characterize are the audience's mental processes in the interpretation of humorous texts.

Underlying this approach to humor lies the premise that communicators can predict and manipulate the mental states of others. Knowing that the addressee is likely to pick out the most relevant

interpretation of the joke (or some part of it), the humorist may be able to produce a text that is likely to lead to the selection of an accessible interpretation, which is then invalidated at some point. In Yus (2003), for instance, it is claimed that in many jokes the initial part has multiple interpretations, which are graded according to their accessibility. The hearer is led to select an overt (i.e., relevant) interpretation of this part of the joke. Suddenly, the hearer notices that the subsequent part has a single covert interpretation which is eventually found to be the correct one (and the one providing a coherent interpretation to the whole text) and which humorously surprises the hearer.

3. **Media discourses.** RT has also been successfully applied to the interpretation of media discourses, including films, newspaper headlines, comics, Internet discourse, and advertising. The last one is probably one of the most extensive applications of the theory. The control over the amount of information provided, the predictability of consumers' responses, and the calculation of the effort required to process information, all typical features of the strategies by the advertisement makers, can easily be analyzed using a relevance-theoretical approach (see Tanaka, 1994).
4. **Literature.** Several studies have applied RT to literary discourse (Pilkington, 2000 is an example). Within an RT approach, literariness has to be analyzed as cognitive effects triggered by textual stimuli, involving special mental processes which, through a relevance-driven cognitive exploration, result in the marginally increased salience of a wide range of assumptions (Pilkington, 2000: 189). Because in literature it is more difficult (if not impossible) to make assumptions mutually manifest, a greater load of responsibility is laid upon the reader in extracting the intended (or, alternatively, his/her own) interpretation of the text, plus whatever feelings and emotions are associated with the comprehension of the text.
5. **Politeness.** This is a typical social feature of communication that somehow appears not to suit the individual-centered approach within RT. However, several studies have attempted an explanation of politeness in relevance-theoretic terms. For instance, politeness has been explained within RT as a verbal strategy compatible or incompatible with the background expectations about the current relationship holding between speaker and hearer, thus leading to different relevance-oriented interpretive paths (see Jary, 1998).
6. **Translation.** In RT-bases studies such as Gutt's (2000), there is a tendency to exploit the idea of

resemblance between the intended interpretations of utterances. (For an account of relevance-theoretic applications to translation.)

Concluding Remarks

In RT, Sperber and Wilson propose a coherent cognitive account of how the human mind proceeds when attempting to select a plausible interpretation of ostensibly communicated stimuli. They rely on the hypothesis that a biologically rooted search for relevance aids human beings in the inferential enrichment of typically underdetermined coded texts and utterances resulting in fully propositional interpretations.

The theory has provided insights in several debates in pragmatics and cognitive science and has been applied to a good number of research areas. Undoubtedly, RT will continue to stir fruitful intellectual debates on the explanation of human communication.

Representation in Language and Mind

F Egan, Rutgers University, New Brunswick, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Languages are human artifacts used for a variety of purposes, most notably, communication. Mental states, such as beliefs, desires, intentions, hopes, and fears – the so-called ‘propositional attitudes’ – are internal states of organisms that are, typically, both effects of external conditions (and other mental states) and causes of behavior. Languages and states of mind are said to ‘represent’ – they can be about things other than themselves. They can even represent nonexistent states of affairs, such as, for example, Superman’s working at the *Daily Planet*. One might wonder how it is possible for linguistic objects – utterances and inscriptions – and states of mind, both of which are physically realized, to represent, i.e., to have meaning or content. And one might wonder how a particular linguistic object or a particular mental state represents what it does. In virtue of what fact, for example, does a thinker’s mental state mean *it will be raining soon*, rather than $2 + 2 = 4$? This tangle of issues is known as the ‘problem of intentionality’.

The Relationship between Language and Thought

It is plausible that representation in language and representation in thought are related. A speaker’s utterances typically express his or her thoughts. One can both think and say that it will be raining soon. Perhaps the limits of language are the limits of thought. Many theorists have found plausible the hypothesis that we can only think thoughts that can be expressed in public language. In any case, a theory of representation should explain how language and thought are related.

Several general strategies for explaining representation in language and mind are possible:

1. Mental representation might be construed as basic or fundamental, and the representational properties of utterances and inscriptions explained in terms of the mental states (beliefs, intentions, and so on) of speakers, hearers, writers, and readers. We shall call such theories ‘mind-based’ theories.
2. Linguistic meaning might be taken as basic and the meanings of mental states explained in terms of the thinker’s linguistic capacities. We shall call these theories ‘language-based’ theories. They have the apparent consequence that nonhuman animals and prelinguistic humans do not have

representational mental states – in other words, they do not literally have thoughts.

3. Neither thought nor language is construed as basic, though there may be some explanatory relations between aspects of each. We will call theories of this third type ‘non-reductive’ theories.

Mental Representation as Basic

The most popular theories of representation are mind-based, construing mental representation as basic and linguistic meaning as derivative of it. This explanatory strategy follows the program set out by Paul Grice in his seminal 1957 paper, ‘Meaning’. Grice provides an analysis of a speaker’s meaning something by an utterance on a particular occasion in terms of the speaker producing an utterance with a set of complex intentions to produce certain states of mind in hearers. Grice’s analysis takes for granted the propositional attitudes of speakers and hearers. The question, then, is how these mental states acquire their meaning.

Some theorists of mind construe mental representation as itself language-like. Thought, they claim, takes place in an inner language or code (*see Mentalese*). Propositional attitudes, in this view, are relations to internal sentences. But whether or not the language-of-thought hypothesis is true, a theory of mental representation requires an account of how propositional attitudes acquire their meaning. And if the account is to serve as the basis for an explanation of representation in public language, then it must not presuppose public language meaning.

Mind-based theories are typically ‘naturalistic’: they aim to explain the intentionality (meaning, aboutness) of a subject’s mental states in terms of non-semantic and non-intentional properties of those states. The intuition behind the naturalistic constraint is clear. An adequate account of intentionality – one that dissolves the air of ontological strangeness surrounding it – should explain it in terms compatible with the broader conception of nature provided by the natural sciences.

Information-Based Theories

Physical systems carry information about the external conditions that impinge on them. The number of rings in a tree’s trunk reliably varies with the number of growing seasons; hence the tree’s trunk carries information about, or represents, the age of the tree. Exploiting this general phenomenon, ‘information-based’ semantic theories take the meaning of a mental state or structure to be determined by the cause of its

tokening in certain specifiable conditions. For example, a mental structure means *cat* if it is reliably caused by the presence of cats.

Mental states not only represent; they can occasionally **misrepresent**. Information-based theories have trouble accounting for misrepresentation. If a given mental structure is reliably caused by the presence of cats, then it is likely to be (reliably) caused by other things in less than optimal conditions, for example, by small dogs on a dark night. Since small dogs on a dark night are among the reliable causes of the structure, then, according to the theory, it means *cat or small dog on a dark night*. Rather than misrepresenting a small dog on a dark night as a cat, the mental state genuinely represents its disjunctive cause. Misrepresentation does not seem possible.

Proponents of information-based theories have attempted to solve the so-called ‘error problem’ by levying additional conditions on the circumstances in which a mental state’s meaning is determined by the cause of its tokening. (See, for example, Fodor’s 1990 account, which requires for a mental structure X to mean *cat* not only that it be reliably caused by cats, but also that if any non-cats cause X, then non-cat’s causing X are **asymmetrically dependent** upon cats causing X; that is, non-cats would not cause X unless cats did, but not vice versa.) Whether these modifications handle the error problem without raising further difficulties is a matter of some dispute.

Teleological Theories

According to ‘teleological’ semantic theories, the meaning of a mental state or structure is determined by its biological function, i.e., that for which it was selected. (See Millikan, 1984, for the most developed proposal of this sort.) A variant of the error problem arises for theories that attempt to ground representation in biological function. A simple example makes the point. A frog will snap its sticky tongue at any fly moving in its vicinity. Some state of the frog’s visual system represents the fly, but is the meaning of this state *fly*, *food*, or – given that the frog will react identically to any small dark object moving in its visual field – *small dark moving thing*? An appeal to the biological function of the frog’s internal state will not settle the issue, as there seems nothing to choose among describing the function of the state as *detecting flies*, as *detecting food* (given that flies are the only available food), or as *detecting small dark moving things* (given that almost all small dark moving things in the frog’s vicinity are flies and hence food). A similar sort of indeterminacy is likely to plague efforts to establish the meaning of states of more complex systems, such as humans. The notion of

biological function seems too coarse an instrument to determine representational content.

Conceptual Role Theories

‘Conceptual role semantics’ (CRS) is the most popular theory of mental representation. Versions of CRS have been developed and defended by philosophers, cognitive psychologists, and (under the guise of ‘procedural semantics’) computer scientists. (See Block, 1986, for a general defense of CRS.) According to CRS, a mental state means what it does in virtue of its causal role in the subject’s mental life. What determines that a mental structure means *cats are furry* is the structure’s role in perception, deductive and inductive inference, deliberation, action, and so on. Tokenings of the structure tend to be caused by the presence of furry cats and to cause one to conclude that if something is not furry then it is not a cat. The causal role of a structure meaning *dogs are needy* involves appropriate relations to dogs and instantiations of the property *neediness*.

A problem for CRS arises from the fact that a mental state’s meaning is determined by the totality of its connections to perceptual stimuli, behavior, and other mental states. In this view, all of a subject’s beliefs involving a concept contribute to its meaning. However, no two people have exactly the same beliefs involving any concept. If I believe that bats are scary but you do not, then, according to CRS, our ‘bat-concepts’ are different. Consequently, our beliefs involving our respective bat-concepts, even such core beliefs as each of us would express by the words ‘Bats are mammals,’ have different content. A consequence of the holistic determination of meaning is that no two subjects will share any concepts or any beliefs.

A proponent of CRS might try various maneuvers to mitigate the effects of holism. It is surely implausible to count every belief as contributing equally to the meaning of a concept. CRS needs some notion of **semantic importance** to distinguish the beliefs that contribute heavily to the meaning of associated concepts from those that do not. Whether such a notion can be spelled out without appeal to semantic or intentional notions – that is, without violating the naturalistic constraint – is an open question.

Constraints on a Theory of Mental Representation

In addition to accounting for the possibility of misrepresentation, and not leading to an unacceptable holism, a theory of mental representation must satisfy a ‘cogency condition’: the interpretation of a subject’s mental states licensed by the theory must, by and large, make sense. The theory must not license an interpretation that makes the subject wildly

irrational. The status of the cogency constraint is a matter of some controversy. Some philosophers (for example, Davidson (1984)) have thought it ‘constitutive’ of the intentional framework that thinkers are, by and large, rational. Others have thought only that, as a matter of empirical fact (perhaps because they are products of evolutionary adaptation), thinkers are typically rational.

An adequate theory of mental representation must also account for the fact that thought is fine-grained. The theory should explain how a thinker can believe that Cicero was a Roman orator but fail to believe that Tully was a Roman orator, even though “Cicero” and “Tully” are names for the same individual. This is known as ‘Frege’s problem’. Finally, as noted above, a theory should explain how thinkers can have thoughts about nonexistent objects or states of affairs, such as Superman’s working at the *Daily Planet*.

Linguistic Representation as Basic

Norms-Based Theories

Language-based theories typically explain mental representation in terms of social practices governing overt speech (see, for example, Brandom, 1994). In this view, the social practices that confer meaning on utterances involve norms governing the correct use of certain expressions and the appropriate consequences of such uses. A given utterance-type justifies (that is, permits) certain other utterances and excludes certain others. A speaker who utters ‘There is a dog’ is committed to the assertion *There are some dogs* and to the denial of *There are no dogs* and is taken to be so committed by others. The relevant norms govern the actions of speakers and hearers, where action is not to be understood as presupposing intentional thought, but rather as behavior shaped by communal practices of conforming and censuring, what Brandom (1994) calls ‘the game of giving and asking for reasons’. It is the communal practice of subjects’ taking each others’ performances as ‘correct’, ‘incorrect’, ‘entitling’, or ‘excluding’ other performances that confers meaning on these performances, and, derivatively, on the subjects’ states of mind. The norms governing these practices make intentionality of both speech and thought possible.

An account of this sort will succeed only if notions of ‘correctness’, ‘entitlement’, ‘commitment’, and so on, can themselves be understood in non-intentional and non-semantic terms. If we must presuppose that the relevant performances – both the utterances themselves and others’ attitudes toward these utterances – are meaningful, if, for example, we must presuppose

that these performances either involve the use of antecedently meaningful expressions or consist in actions produced with certain intentions in mind, then their meaningfulness does not reside in, or result from, the conforming and censuring practices themselves. The project fails if the social practices that supposedly confer meaning cannot be explained without presupposing that the performances governed by these practices have meaning. It is not obvious that this explanatory burden has been discharged.

A Non-Reductive Proposal

A non-reductive construal of the norms-based project is possible. One might see the task of articulating the structure of the norms governing overt speech as exposing how the intentionality of thought and the (public) norms governing overt speech are intimately connected. Such an account would aim to show that we cannot understand representation, in either language or thought, without a notion of inference, that is, without the idea of certain claims entitling or justifying others. (This idea is a cornerstone of the CRS developed by Wilfred Sellars.) On this construal, the project is an attempt to work out the interconnections between language and thought, without taking either as basic.

Rigid Designation

S Predelli, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Rigidity is a semantic notion. Semantics studies the relationships between expressions in a language and (typically) extralinguistic items. Examples of semantically interesting features are the relationship between the name ‘George Bush’ and Bush, the individual to which it refers; the relationship between the sentence ‘George Bush is a liberal’ and falsehood, its truth value; and, at least in some views, the relationship between the definite description ‘the President of the United States’ and Bush, the individual it denotes.

The task of a semantic theory is not that of immediately assigning the aforementioned features to the appropriate expressions. For instance, that the sentence ‘George Bush is a liberal’ is to be assigned falsehood depends not only on the semantic traits of the expressions under analysis, but also on obviously extrasemantic facts having to do with Bush’s political convictions. By the same token, that the *denotatum* of ‘the President of the United States’ is George Bush, rather than John Kerry or myself, also depends on extrasemantic facts having to do with the results of the latest presidential election. For this reason, the aim of a semantic theory is that of presenting *relativized* assignments of semantic features. For instance, what our theory may conclude is that ‘George Bush is a liberal’ is true with respect to all and only those parameters that provide a positive reply to the query about Bush’s leftist tendencies, and that ‘the President of the United States’ denotes Bush with respect to all and only those parameters with respect to which Bush won the presidential elections. According to a customary approach, parameters of this type may be understood as possible worlds. In a more complex framework, the *relata* appropriate for semantic evaluation may include, together with possible worlds, a temporal parameter: for instance, ‘the President of the United States’ may denote Bush with respect to a given possible world and a certain time, but Bill Clinton with respect to that world and another time span.

Let me refer to the semantic features for the aforementioned expressions as their semantic value: so, the semantic value of a sentence (with respect to a possible world and/or a time) is its truth value (with respect to that world and that time); the semantic value of a definite description (with respect to a possible world and/or a time) is its *denotatum* (with respect to that world and that time); and so on. In general, and leaving momentarily aside a few interesting complications, an expression is rigid with respect to a parameter *k* if it has the same semantic value across all *ks*. For instance, an eternally true sentence is temporally rigid: its truth value is constant across all times. Since in what follows I leave temporal considerations out of the picture, I employ the expression ‘rigid’ *tout court* as alluding to constancy of semantic value across possible worlds.

Names and Rigidity

Two kinds of singular designators, namely names and definite descriptions, have been singled out as paradigmatic of the rigid/nonrigid divide. As I hinted, typical definite descriptions such as ‘the President of the United States’ are nonrigidly associated with distinct *denotata* with respect to different possible worlds. But proper names such as ‘George Bush’ apparently rigidly persist in referring to Bush with respect to all possible worlds (or, at least, all possible worlds in which Bush exists; more on this *caveat* later). For instance, if you are interested in evaluating ‘George Bush is wise’ with respect to a counterfactual scenario as dramatically different from the actual world as you may like, what you need to consider is whether, given the collection of individuals that are wise in that scenario, Bush is one of them (see Kripke, 1980).

One possible source of confusion must be cleared from the outset: what is at issue is not the question of who happens to be called ‘George Bush’ in the scenarios under consideration: that in some merely possible world certain expressions may be endowed with a different meaning, and certain names may be used to refer to alternative individuals is of no relevance for our purpose. Similarly irrelevant is the possibility that, in our actual employment of ‘George Bush’, different individuals may be referred to by that name type.

Types of Rigidity

I wrote that typical definite descriptions behave non-rigidly. This does not entail that there may not be rigid definite descriptions. For instance, ‘the positive square root of four’ denotes the number two with respect to any possible world and is thus a rigid designator. It seems clear that this expression’s rigidity derives not directly from its semantic behavior, but from the modal perseverance of the mathematical world. The description ‘the positive square root of four’ interacts with the parameter with respect to which it is evaluated as any other description would: a certain condition is being put forth, in this case that of being the positive square root of four, and an individual is selected on the basis of its ability to satisfy that condition. The description is, in a sense, semantically available for a nonrigid profile. Its rigidity is a result not of its semantic behavior, but of the response that alternative possible worlds provide: one and the same item, the number two, is inevitably being offered as the description’s *denotatum*.

Saul Kripke refers to descriptions such as ‘the positive square root of four’ as rigid only *de facto*. Expressions such as proper names, namely expressions whose semantic profile presumably guarantees their rigidity, are classified as rigid *de jure* (Kripke, 1980). Note that in this understanding of the *de facto/de jure* distinction, not all rigid descriptions are rigid merely *de facto*. For instance, the description ‘the actual President of the United States’ rigidly refers to a certain individual by virtue of its semantic behavior, in particular by virtue of the meaning of the indexical expression ‘actual’ (see Kaplan, 1977; Lewis, 1970).

Thus far, I rested satisfied with the notion that a rigid expression has a constant semantic value across possible worlds, and, in particular, that a rigid designator designates the same individual with respect to any possible world in which that object exists (Kripke, 1980; see also Kaplan, 1977). When it comes to the decision about an expression’s semantic value with respect to possible worlds in which that object fails to exist, two options may be entertained. In the terminology from Salmon (1981), a designator is **persistently** rigid iff it designates its *designatum* *x* with respect to any world in which *x* exists and designates nothing with respect to any world in which *x* does not exist. On the other hand, a designator is **obstinately** rigid iff it designates *x* with respect to every possible world, regardless of whether *x* does or does not exist in it.

Rigidity has played an important role in one of the central semantic debates during the seventies and

eighties, having to do with descriptivist views of customary proper names, such as, presumably, Frege’s and Russell’s. If proper names are rigid but typical descriptions are not, so the story goes, proper names may not behave in the manner descriptivists envisage. (For a critical discussion of a descriptivist reply, to the effect that proper names are associated with rigid descriptions, see Salmon, 1981; Soames, 1998.) Other important themes linked to the notion of rigidity have to do with the hypothesis that natural kind terms, such as *tiger* or *gold*, also behave rigidly (see Kripke, 1980; for a detailed discussion of the difficulties in extending the classic definition of rigidity to kind terms, see Soames, 2002). Finally, the idea of rigidity and the distinct but related notion of direct reference occupy center stage in the semantic analysis of indexical expressions. (On the relationships between rigidity and direct reference, see Marti, 2003.) For instance, an indexical singular term such as *I* rigidly refers (with respect to a given context *c*) to the agent of *c*, that is, at least in typical instances, to the person who is speaking. The notion that indexicals such as *I* behave rigidly, even though they are associated with a descriptive meaning, plays a crucial role in the classic arguments for the distinction between meaning and content or, in David Kaplan’s classic vocabulary, between *character* and *content* (see Kaplan, 1977; Lewis, 1980).

Rules and Rule-Following

A Miller, Macquarie University, Sydney, NSW, Australia

© 2006 Elsevier Ltd. All rights reserved.

Why are the notions of rules and rule-following of significance to the philosophy of language and linguistics? Inspired by the discussions of rule-following in Wittgenstein's *Philosophical investigations* (sections 138–242) and *Remarks on the foundations of mathematics* (section VI), Saul Kripke and Crispin Wright independently developed arguments that challenged our intuitive conception of *meaning* as both *factual* and *objective* (see Wright [1980], Chapters 2 and 12, and Kripke [1982]). In this article, we will focus on the rule-following issue as presented by Kripke.

Rule-Following and Meaning

Suppose that Jones intends to follow the rule 'Add 2' in continuing the series: 2, 4, 6, 8, 10, Jones can continue the series in ways that *accord* or *fail to accord* with the requirements of the rule. For example, the continuation 12, 14, 16, . . . would accord with the rule (as standardly understood), whereas the continuation 12, 13, 14, . . . would fail to accord with the rule (as standardly understood). In other words, the former continuation would be *correct* by the lights of the rule, whereas the latter would be *incorrect* by the lights of the rule: the rule provides a *normative standard* against which particular continuations can be assessed as correct or incorrect. Intending to follow a rule is analogous in certain respects to meaning something by a linguistic expression. The meaning of a linguistic expression provides a normative standard against which the uses of that expression can be assessed as correct (or incorrect), as according with that meaning (or failing to accord with that meaning). Thus, for example, given the usual meanings of the numerals and signs involved, and given the arithmetical fact that the sum of 68 and 57 is 125, the answer '125' to the query '68 + 57 = ?' will be correct by the lights of those meanings, whereas the answer '5' will be incorrect by the lights of those meanings.

Suppose that Jones has laboriously written out the series 2, 4, 6, 8, . . . , 996, 998. Is there a fact of the matter as to what rule he's been following in writing out this sequence? Ordinarily, we'd be inclined to say that there is a fact of the matter, and, that, in all likelihood, he's been following the rule 'Add 2' (and not, say, the rule 'add 3,' or not following any rule at all but simply writing down numerals at random). According to Kripke's Wittgenstein

(hereafter 'KW'), this is an illusion: there is no fact of the matter as to what rule Jones has been following, and indeed no fact of the matter as to whether Jones has been following any rule at all. In similar fashion, we can ask whether there is a fact of the matter as to what meaning Jones associates with the '+' sign. Assuming that Jones's uses of the '+' sign have been roughly similar to our own, we'd be inclined ordinarily to say that there is a fact of the matter, and, that in all likelihood, he understands '+' to mean the *addition* function (and not, say, the multiplication function or no function whatsoever). As in the case of rules, KW claims that this is an illusion: there is no fact of the matter as to what Jones means by '+,' and indeed no fact of the matter as to whether he means anything at all by '+.'

Constitutive and Epistemological Skepticism

Before turning to KW's argument, we need to note a distinction between two types of skepticism. An *epistemological skeptic* about a particular area claims that we are not entitled to the knowledge claims that we typically make within it. Thus, for example, an epistemological skeptic about the external world (such as the skeptic who is Descartes's protagonist in his *Meditations*) would argue that I am not entitled to claim that I know that I am currently awake and sitting at a computer writing a philosophy essay. The epistemological skeptic doesn't question whether there is a fact of the matter as to whether I'm currently awake: he's happy to concede that there is a fact of the matter (either I'm awake, etc., or I'm not), and questions only whether I'm entitled to say that I know which of the two relevant possibilities is actually the case. KW's *skepticism about rule-following and meaning is not only epistemological skepticism*. KW argues, not only that we don't know whether we mean addition by '+,' or intend to follow the rule 'Add 2,' but also that there may not be anything to know. That is, not merely are we ignorant about what '+' means; there is no fact of the matter as to what it means – there is nothing for meaning facts to consist in or to be constituted out of. KW is thus a *constitutive skeptic* about rule-following and meaning. But as we'll see, KW takes an epistemological route to his constitutive skepticism.

KW's Skeptical Argument

Suppose that, in the examples above, Jones has never previously gone beyond 996 in his apparent attempts

to continue the arithmetical series generated by the rule 'Add 2,' and has never performed arithmetical calculations with numbers greater than 57 (the fact that Jones is a finite creature ensures that we can always set up this sort of scenario simply by choosing numbers that are large enough). If there were a fact of the matter as to what rule Jones is trying to follow, or a fact of the matter as to what meaning he associates with the '+' sign, there would be a fact of the matter as to how he ought to continue the number series (if he is to accord with the relevant rule), and a fact of the matter as to how he ought to answer the query ' $68 + 57 = ?$ ' (if his practice is to accord with the relevant meaning). KW argues that there is no fact of the matter as to how he ought to continue the number series, and no fact of the matter as to how he ought to answer the query ' $68 + 57 = ?$ '. Who is to say that Jones does not, in the case of the number series, intend to follow the rule 'Zadd 2,' in which the result of zadding 2 to a number is the same as the result of adding 2 to a number for numbers less than 1,000 and the same as the result of adding 4 to a number for numbers greater than or equal to 1,000? If Jones intended to follow this non-standard rule in continuing the series, he ought to continue the series 998, 1000, 1004, 1008, ... and not as we'd expect, namely 998, 1000, 1002, 1004, 1006 ... and so on. Likewise, who is to say that Jones does not, in the case of the arithmetical calculation, understand '+' to mean, not the addition function but, rather, the *quaddition* function, in which the result of *quadding* two numbers x and y is the same as adding them when both x and y are less than 57 but, rather, 5, when either x or y is greater than or equal to 57? If Jones meant the quaddition function by the '+' sign, he ought to answer '5' to the query ' $68 + 57 = ?$,' and not, as we'd expect, '125.'

KW's argument proceeds by allowing us *unlimited and omniscient access* to two broad categories of fact, and invites us to find the fact that constitutes Jones's intending to follow the 'Add 2' rule as opposed to the 'Zadd 2' rule, or Jones's meaning addition as opposed to quaddition by '+': facts about Jones's previous behavior and behavioral dispositions and facts about Jones's mental history and mental states. The assumption is that if facts about rule-following and meaning are to be found anywhere, they will be found within these two kinds of fact. So, if unlimited and omniscient access to these two classes of fact fails to turn up a fact that constitutes Jones's intending to follow one rule rather than another, or meaning one thing rather than another, it will follow that there is simply no such fact to be found. This is why we said above that KW's argument for constitutive skepticism proceeds via an epistemological route: KW argues

that even given unlimited and omniscient access to facts about Jones's behavior and behavioral dispositions and facts about Jones's mental life, we still couldn't claim to know, or justify, a particular hypothesis about how Jones ought to continue the arithmetical series or answer the arithmetical query.

Facts about Jones's previous behavior won't do the trick, as all of that behavior is consistent with Jones's intending to follow the 'Zadd 2' rule or meaning the quaddition function by the '+' sign: *ex hypothesi*, he had never previously dealt with cases in which the numbers were large enough for 'Add 2' and 'Zadd 2,' or meaning addition and quaddition, to demand different responses (Kripke, 1982: 7–15). Facts about how Jones is disposed to continue the series, or answer arithmetical queries, won't turn the trick either. Even if it was true that *if* Jones had reached 1000, he *would* have continued 1004, 1008, and so on, or true that *if* he'd been asked ' $68 + 57 = ?$ ' he *would* have answered '125' and not '5,' neither of these facts could plausibly be said to constitute his intending to follow one rule rather than another, or mean one function rather than another. Facts about the rule he intended to follow, or the meaning he attached, are *normative* facts, facts about how he *ought* to continue the number series or answer the arithmetical query. But the dispositional facts canvassed tell us at most what he *would* do in certain situations, as opposed to telling us what he *ought* to do in those situations (Kripke, 1982: 22–38). KW also rules out the following as facts constitutive of rule-following and meaning: *general thoughts* or *instructions* (1982: 15–17); relative *simplicity* of hypotheses about rule-following and meaning (1982: 38–40); *qualitative, introspectible, irreducibly mental states* (such as mental images) (1982: 41–51); *sui generis and irreducible mental states* (1982: 51–53); relations to *objective, Fregean senses* (1982: 53–54). Thus, according to KW there are no facts about rule-following and meaning, and these notions vanish 'into thin air' (1982: 22).

KW's Skeptical Solution

KW describes this result as a 'sceptical paradox,' and attempts to avoid the 'insane and intolerable' (1982: 60) conclusion that 'all language is meaningless' (1982: 71) via a 'sceptical solution.' The main idea of the skeptical solution is that judgments about rule-following and ascriptions of meaning can be viewed as possessing a *non-fact-stating role*, so that the practices of ours involving the notions of rule-following and meaning avoid the worries associated with the skeptical paradox. If the function of judgments about meaning is not to describe facts, the discovery that

there are no facts about meaning no longer threatens our practice of making such judgments. It emerges as a consequence of the detail of the skeptical solution that the notions of rule-following and meaning only have application relative to *communities* of rule-followers or speakers, not absolutely. In particular, it follows that 'solitary' language is impossible. (This is KW's take on Wittgenstein's famous 'private language argument'.)

Significance of the Issue

Unless it is blocked, the skeptical paradox threatens to undermine the idea that we can give a *cognitive-psychological* explanation of, for example, semantic creativity: the capacity speakers' have to understand novel utterances. One way of essaying such an explanation would be in terms of speakers' knowledge of the meanings of the familiar constituents of the novel utterance and their proceeding from this to knowledge of the utterance's meaning in a way that mirrors the compositional route to the meaning of the utterance from the meanings of its constituents and their mode of syntactic combination. Clearly, if there are no facts about meaning there will be no facts about the meanings of novel utterances or their constituents, so that the whole project of cognitive-psychological explanation of semantic creativity will be undermined. That would be a consequence of the skeptical paradox about meaning. But the skeptical paradox about rule-following in general would have even more destructive consequences: one way of attempting to explain the capacity speakers have to distinguish grammatical from ungrammatical strings would proceed in terms of their implicit grasp of grammatical rules governing the language in question. Clearly, if there are no facts of the matter as to whether these rules classify a given novel string as grammatical or not, this whole project, too, will be thrown in jeopardy. For a particularly clear exploration of these issues, see Wright (1989). See also Baker and Hacker (1984).

Responses to the Skeptical Paradox and Skeptical Solution

For defenses of dispositionalist, or otherwise naturalistic, solutions to KW's skeptical paradox, see Forbes (1984), Fodor (1990), Millikan (1990), and Horwich (1998). For further discussion of dispositionalism, see Boghossian (1989: Section V), McManus (2000), and Miller (2003). For non-reductionist responses (according to which facts about meaning are not reducible to facts about non-semantically and

non-intentionally characterized behavior or states), see McDowell (1984), McGinn (1984), Wright (1989), Boghossian (1989: Section VI), and Pettit (1990). Wright takes the rule-following arguments to threaten, not the factuality of meaning but, rather, the *objectivity* of meaning: see the Introduction to Wright (1993). For discussion of the skeptical solution and the argument against solitary language, see Blackburn (1984), Wright (1984), and Boghossian (1989: Sections II–IV). KW's skeptical solution was characterized above as a version of non-factualism about ascriptions of meaning, but this interpretation has been challenged by a number of philosophers: see, e.g., Wilson (1994) and Kusch (in press). For a searching examination of the normativity of meaning, see Hattiangadi (in press). For a reaction to KW from the perspective of a linguist, see Chomsky (1986). For an introductory survey and overview, see Miller (1998: Chaps. 5 and 6).

Saussure: Theory of the Sign

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The sign theory of Ferdinand de Saussure (1857–1913) is principally to be found in his *Cours de linguistique générale* (*Course in General Linguistics* 1916; translated into English in 1959 and 1983). Saussure's previous work in philology and his focus on the development of Indo-European languages necessarily contains ruminations on the vicissitudes of the linguistic sign but it was his delivery of the course in general linguistics, at short notice to replace a sick colleague, at the University of Geneva from 1907 to 1911, which established his thought in this area. His posthumously published treatise of 1916 was based not on his own writings but on the notes of students present at the course. Specifically, the course was 'reconstructed' for publication by Charles Bally and Albert Sechehaye who stated in their introduction that they were aware of their responsibility to the author who "perhaps might not have authorized the publication of this text" (Saussure, 1983: xx).

The preliminary fact that needs to be taken into account, then, in relation to Saussurean sign theory is that, from the outset, it was never definitive. Readers of the *Cours* cannot be confident that Saussure's exact words are reproduced in full. Furthermore, they cannot be sure that the editorial choices of Bally and Sechehaye were not limited by what was available to them. For example, a notebook of notes in Saussure's hand, unknown to the editors, was discovered in 1996 and may force a re-reading of previous understandings of Saussurean sign theory. More important still, perhaps, is that Saussure's work has been refracted through the work of many illustrious successors beyond the realms of academic linguistics. While Saussure's *Cours* is just one, somewhat fragmented, publication that is still insufficiently read by those dabbling in sign study, the publications and teachings of his successors (or those who have invoked his name) have reached far wider audiences. The latter have had the benefit of an age of media saturation as well as a growing preoccupation with

the aspects of communication that lie beyond the objects of linguistics. It is difficult to talk about Saussure's sign theory, then, without mentioning that there is also the Saussurean sign theory of Karcevskij, Vološinov, Jakobson, Benveniste, Hjelm-slev, Lévi-Strauss, Lacan, Barthes, Mounin, Chomsky, Derrida, and Baudrillard, to name but a few. (Incisive discussions of a number of these are to be found in Harris, 2003).

Saussure's *Cours* projects "a science *which studies the role of signs as part of social life*" (Saussure, 1983: 15) early in the introduction, but the focus on the linguistic sign appears in Part One on General Principles. From the beginning, Saussure makes it clear that a linguistic sign is not "a link between a thing and a name, but between a concept and a sound pattern" (Saussure, 1983: 66). Moreover, "the sound pattern is not actually a sound; for a sound is something physical" (Saussure, 1983: 66). He therefore stresses that "This sound pattern may be called a 'material' element only in that it is the representation of our sensory impressions" (Saussure, 1983: 66). The linguistic sign is thus a "two-sided psychological entity" (see Figure 1).

It should be clear, then, that Saussure is not pursuing the relation between a thing in the world and the way that it is designated, but a psychological entity that amounts to signhood.

Proceeding to refer to the sound pattern as the *signifiant* and the concept as the *signifié*, Saussure makes clear that the former is in the mind and represents sensory impressions of sound outside the mind, while the latter consists of an abstract formulation of phenomena in the world such as 'house,' 'white,' 'see' and so forth (Saussure 1983: 65, 101ff). Saussure insisted that there was a *signifié* bound to each *signifiant* but that the reasons for their binding was not natural or pre-ordained. This fact is the first of the two fundamental characteristics of the sign: that the relation in the sign is arbitrary. He writes,

There is no internal connexion, for example, between the idea 'sister' and the French sequence of sounds *s-ö-r* which acts as its *signifiant*. The same idea might as well

Figure 1 The linguistic sign as a “two-sided psychological entity” (cf. Saussure, 1983: 67).

be represented by any other sequence of sounds. This is demonstrated by differences between languages, and even by the existence of different languages. The signification ‘ox’ has as its signal *b-ö-f* on one side of the border [between French- and German-speaking regions] but *o-k-s* (Ochs) on the other side. (Saussure, 1983: 67–68; the terms *signifiant* and *signifié* are left in the original with the permission of the translator.)

To use another example, the connection between a *signifiant* ‘duck’ and the concept of ‘duckness’ was seen to be specific to the development of particular national languages. Nevertheless, Saussure did consider possible deviations from this principle, such as onomatopoeic words or signs such as those used in mime. These, somehow, seem to have a bearing which, to an extent, does suggest a preordained relationship of *signifiant* and *signifié*. But they are only deviations from the main rule. Tellingly, then, Saussure insisted that “when semiology is established . . . the main object of study in semiology will none the less be the class of systems based upon the arbitrary nature of the sign” (Saussure, 1983: 68).

The second principle upon which Saussure insisted was the linear character of the *signifiant*. This has not been the focus of semiology in the same way as the first principle has, but is nevertheless important. Saussure says that the linguistic *signifiant*, “being auditory in nature, has a temporal aspect” (Saussure, 1983: 69). What the principle of temporality entails is that the auditory sign can only exist in a linear fashion. Unlike graphic signs, it is always part of a chain unfolding. Pictures can present elements simultaneously; sounds have to wait for the connections to mount up one after another. Saussurean theories of the sign that attempted to look at nonverbal semiosis tended to elide this observation of Saussure.

Saussure insisted on four crucial factors inherent in the function of the sign:

- The arbitrary nature of the linguistic sign

- The great number of signs necessary to constitute a language
- The complex character of the system
- Collective inertia resists all linguistic innovations (Saussure, 1983: 73–74).

All of these bear upon whether the character of signs can be changed individually, a question Saussure answers in the negative. Arbitrariness seems to suggest that the sign allows free choice; however, Saussure emphasizes that words are fixed by our ancestors and that the effort required to change them is considerable and necessarily collective. This issue of freedom and its restrictions also bears upon some crucial distinctions in Saussure’s *Cours* that frame his theory of the sign. For Saussure, there is an emphatic difference between *langue* and *langage*. Rendering both terms accurately in English is difficult, but *langage* refers to a linguistic faculty of humans that *requires a langue* among its community of speakers. *Langage*, then, comprises two things. The first is the aforementioned *langue* – the differences between all signs (with their arbitrary relations), a set so multifarious and interconnected that it amounts to a system. This collective phenomenon, potentially available to, and stemming from, all “takes the form of a totality of imprints in everybody’s brain, rather like a dictionary of which each individual has a copy” (Saussure, 1983: 19). The second is *parole* – the sum total of what people say, and it comprises (a) individual combinations of words, depending on the will of the speakers, and (b) acts of phonation, which are also voluntary and necessary for the execution of the speakers’ combination of words” (Saussure, 1983: 19).

Saussure emphasizes that “there is nothing collective about speech” (Saussure, 1983: 19); *langue*, however, is precisely a matter of the collectivity, the system of differences shared by all speakers. *Langue*, in fact, is the system upon which the signs in individual speech acts is predicated. Harris writes:

The priority of *langue* as far as (Saussurean) linguistics is concerned can be boiled down to the proposition that if any episode of human speech is to be the subject of serious scientific inquiry it must be related in the first instance to a system which must be presupposed as underlying it (Harris, 2001: 121).

This is not the only way in which ‘choice’ over signs is subordinate to the system for Saussure.

Saussure indicates that speakers can combine linguistic signs into an infinite number ‘syntagmatic’ sequences, a fact that points to a certain amount of freedom. Such sequences – syntagmas, as Saussure calls them (Saussure, 1983: 121) – are bound by relations of combination. These relations exist to

facilitate the combinations **within** words and also **between groups of words**. (Within words, certain suffixes or prefixes might be subject to combinations, e.g., the suffixes *-ly* or *-less* with *name*; between words, certain combinations might be almost unavoidable, e.g., *dint* is very seldom seen without *by* preceding it and *of* succeeding it). Yet both are also subject to associative relations (Saussure, 1983: 123–124), or associations in the mind. Thus *-less* is not just a syntagmatic relation with *name*: it is also in an associative relation with all other uses of *-less* such as *blameless*, *feckless*, *careless*. Or, an associative relation may be in operation at the level of connectedness of concepts: *teaching*, *instruction*, *apprenticeship*, etc. (Saussure, 1983: 124). This has important consequences for the role of the sign in *langue* and *parole*. Saussure introduces the sentence, phrase, or clause as an example of a syntagma, but seems to hold back from suggesting they are always the subject of individual innovations. For Saussure, it seems that some combinations are a product of both *langue* and *parole*. Post-structuralists tend to suggest that ‘discourse’ (meaning many things, but frequently referring to the phrase, sentence, or larger syntagma) is an arena of choice or determination beyond the realms of *langue*. This is a matter that is implicitly taken up by a number of ‘Saussurean’ theories of the sign. What is apparent, though, in respect of the *Cours*, is that the status of *langue* as the fundamental system of signs is drawn into question by the possibility that it may be implicated with choice in syntagma production.

The role of the ‘value’ of the sign is clearer. Although combination is integral to Saussure’s sign theory, he insists that individual signs do not have ‘meaning’ or intrinsic identity. Rather, *langue* is a system of values: “A language is a system in which all the elements fit together, and in which the value of any one element depends on the simultaneous coexistence of all the others” (Saussure, 1983: 113). This is schematized in Figure 2.

Clearly, values arise from the relationships between whole signs. Yet these relationships are based on two key points:

Values always involve:

- something dissimilar that can be exchanged for the item whose value is under consideration, and

- similar things that can be compared with the items whose value is under consideration.

These two features are necessary for the existence of any value. To determine the value of a five-franc coin, for instance, what must be known is (1) that the coin can be exchanged for a certain quantity of something different, e.g., bread, and (2) that its value can be compared with another value in the same system, e.g., that of a one-franc coin, or of a coin belonging to another system (e.g., a dollar). Similarly, a word can be substituted for something dissimilar: an idea. At the same time it can be compared to something of like nature: another word (Saussure, 1983: 113–114).

Saussure is therefore keen to emphasize the system of values rather than the intrinsic meaning of signs. Thus, famously, he notes the value of the French word *mouton*, which carries both the animal to which it refers (the sheep) and the meat that comes from it (mutton); whereas the English word *sheep* has a different value because it needs to be supplemented by an additional word, *mutton*, to refer to the animal’s meat.

Saussure’s conclusion on value is that “In *langue* there are only differences, and no positive terms” (Saussure, 1983: 118). Putting this more broadly, he argues that “In a sign, what matters more than any idea or sound associated with it is what other signs surround it” (Saussure, 1983: 118). Effectively, if one were looking for it, this is the crux of Saussure’s sign theory and what imputes to it a particular character. One could argue that it is certainly the feature that seems to have drawn other ‘Saussurean’ sign theories to the *Cours* like a moth to a flame. Indeed, Saussure’s sign theory cannot really be considered without taking into account the many extensions, bowdlerizations, revisions, and plain distortions that it has suffered. Saussure’s *Cours* was rapidly taken up in many different ways, a fact that was not without its problems. Roy Harris writes:

Within five years of its publication Saussure’s *Cours* had become widely read in linguistic circles (De Mauro, 1972: 366). Translations into various languages followed. An initially critical reception gradually yielded to acceptance. By 1957 (centenary year of the eponymous Saussure’s birth) it was possible for a professional academic linguist to write: ‘We are all Saussureans now’ (Spence, 1957). But whether they all were – and, if so, to what extent – are tricky questions (Harris, 2001: 118).

Figure 2 A system in which all the elements fit together (cf. Saussure, 1983: 113).

An early enthusiast for the *Cours* was the Russian, Sergej Karcevskij (1894–1955) who had attended Saussure's courses in Geneva and spread the word of their import back to Moscow in 1917. Saussurean sign theory was thus conveyed to the Moscow Linguistic Circle, featuring the young Roman Jakobson (1896–1982) and to OPOYAZ, a society that featured the Russian Formalists. One of the first major extensions of Saussure's theory of the sign, however, emanated from elsewhere in Russia. In fact, it was part of a penetrating critique by the Soviet theorist Valentin Vološinov. Vološinov (1895–1936), who had written a number of articles since 1922, published two books in the Soviet Union: in 1926, *Freudianism: a critical sketch* (1987) and, in 1929, *Marxism and the philosophy of language* (1973). Both remained virtually unknown for three decades except for the enthusiasm about the latter that was generated by Roman Jakobson in his communications to the Prague Linguistic Circle in the 1930s (Titunik, 1987: xv). At about the time that Vološinov was rediscovered in the Soviet Union, coinciding with the renaissance of Soviet semiotics (see Lucid, 1988) and leading to the translation into English of *Marxism and the philosophy of language* (1973), a number of sources began to argue that the author of Vološinov's works was none other than Mikhail Bakhtin (1895–1975) (see Todorov, 1984: 6–13).

Vološinov proceeds from an understanding of the linguistic sign as totally shot through with the social world from the outset. In fact, he devotes a considerable amount of time to criticizing "individualistic subjectivism" in the philosophy of language for simply studying words/utterances without the social dimension. His other target is the Geneva school (Saussure and his students, Bally and Sèchéhayé) as representative of "abstract objectivism." Saussure's *Cours* is 'abstract' because it does not take as its main focus concrete utterances, opting, instead, for 'form' (*langue*, the non-concrete system of differences) as the basis of language study. It is 'objectivist' because it promotes the idea that this form rules concrete utterances and is the common denominator of all meaning among all people. In general, the *Cours* is argued to err in suggesting that the social world is constituted in the shared system *langue*. For Vološinov, actual utterances (*parole*) must be understood in terms of the role played by a speaker and listener: "A word is a bridge thrown between myself and another . . . A word is a territory shared by both addresser and addressee, between the speaker and his [or her] interlocutor" (Vološinov, 1973:). All signs are built to be received, even if the identity of the receiver is unclear or he or she is not present; what

is important is that speaker and listener are bound in a social relationship that derives from both the utterance of signs and the wider set of social relationships in which the verbal interaction takes place. What is influential in Vološinov's *Marxism and the philosophy of language*, found also in Bakhtin, but arguably derived from dialogue with Saussure's *Cours*, is a 'dialogic' theory of the word.

Whereas Saussure sees instances of *parole* as being generated by a set of differences (in *langue*), Vološinov sees them as products of social situations. For Saussure, then, the production of utterances is ruled by purely formal laws while for Vološinov it is ruled by the multifarious nature of 'ideology.' 'Ideology' is to be understood here, as Vološinov makes clear at the beginning of *Marxism and the philosophy of language*, as both a part of reality and a reflection and refraction of a wider reality by means of signs (Vološinov, 1973: 9). Ideology is not to be understood as consciousness but as a sign system like that which makes up utterances; moreover, it fills the territory that is engendered by a verbal interaction. This, Vološinov argues, is because speakers and listeners are not concerned with the form of language, nor do they utter or hear 'words' as such; rather, they say and hear "what is true or false, good or bad, important or unimportant, pleasant or unpleasant, and so on" (Vološinov, 1973: 70). It is for this reason that any analysis of language must take into account the "common spatial purview of the interlocutors," "the interlocutors' common knowledge and understanding of the situation" and "their common evaluation of that situation" (see Vološinov, 1987).

In *Marxism and the philosophy of language*, Vološinov had also introduced 'theme,' 'meaning,' and accent,' concepts that indicate the material fashion in which meaning is different each time an utterance occurs because the situation is different on every occasion. The term 'meaning' is quite a problematic one for both Vološinov and Saussure: the latter insists on 'value' rather than 'meaning' as the distinguishing attribute possessed by a sign in a system of differences; likewise, Vološinov denies the possibility that a sign can have 'meaning' on its own. But whereas Saussure locates 'value' in the interaction of signs, Vološinov finds that 'meaning' is only part of a 'theme' that resides in the whole interaction between speakers. Moreover, 'meaning' is subject to the specific socially oriented intonation of utterances that Vološinov names 'accent.' When two people are in a room and the single word 'Well' passes between them, what does it mean? Saussure had maintained that the linguistic sign was an entity that was

collective by virtue of its existence in *langue*. Yet, the collectivity that enthuses the *Cours* was not enough for Vološinov, simply because it was ‘abstract’ rather than concrete.

Marxism and the philosophy of language contained a major critique of Saussurean sign theory but, nevertheless, can be argued to be an extension of it. In his positing of ‘theme’ and ‘meaning,’ the latter might be said to be concurring with the general principle of Saussure’s notion of *langue*. Similarly, Vološinov does not deny that there are instances of *parole* that are generated from existing potentials. However, there would always be one factor distinguishing Vološinov’s position from that of Saussure: for a sociolinguistic theory such as Vološinov’s, performative rules or a system of differences are insufficient for analyzing the fortunes of the linguistic sign (Vološinov, 1987: 99).

Although Vološinov’s critique of Saussure is often taken to be one of the first extensions of the latter’s sign theory that has impinged upon contemporary semiotics, the closely argued essays on linguistics of Emile Benveniste (1902–1976) were taking Saussure’s theory of the sign as their impetus. Benveniste was an Egyptian-born French linguist and defining figure in the thought of postwar France and beyond. Clearly, he is the father of post-structuralism, his work from the late 1930s onward paving the way for the critiques of structuralism offered by the likes of Derrida, Lacan, Kristeva, the later Barthes, Baudrillard, and assorted Anglo-American theorists in studies of film, literature, and philosophy (see Easthope, 1988). The essays in *Problèmes de linguistique générale* (1966, translated into English in 1971) ranged from a penetrating critique of Saussure’s principle of arbitrariness in the sign, ‘The nature of the linguistic sign,’ through a series of extensions of Saussurean sign theory. These include consideration of the general role of prepositions, ‘The sublogical system of prepositions in Latin,’ to his essay on the third person as a non-person, ‘The nature of pronouns.’

Benveniste argued in ‘The nature of the linguistic sign’ that the relations between the sound pattern of a sign and the mental concept attached to it were far from being arbitrary in experience. Where Saussure had insisted that the connection between a signifier and a signified was not a ‘natural’ one, rather it was based on convention or habit, Benveniste argued first that the arbitrary relation is one that exists between the whole sign and the object in the real world that it refers to. Relations between the *signifiant* and *signifié*, however, are not arbitrary at all for language users; in fact, the sound pattern and the concept almost seem to be as one in the human mind. In fact,

the creation of a concept in the human mind that is bound with a sound pattern is rehearsed so often at an early age that it becomes an almost instantaneous process. The individual sign user cannot change the relation in English between the *signifiant* of *duck* and its *signifié*. Consequently, Benveniste’s essay concludes, the connection between a sign’s sound pattern and the concept with which it is bound seems almost natural and should, more accurately, be stated as a necessary rather than an arbitrary relation.

‘The nature of the linguistic sign’ is characteristic of Benveniste’s take on linguistics: his extensions of Saussure are invariably conducted in an effort to apprehend the user’s feelings in language. Benveniste’s concern with the way in which signs work for the human subject points the way to further influential explorations of (post) Saussurean sign theory. In his essays on ‘Subjectivity in language’ and ‘The nature of pronouns’ collected in *Problèmes de linguistique générale*, Benveniste sought to demonstrate how signs under certain linguistic categories not only allow human subjects to refer to themselves but actually create the parameters of human self-consciousness. He writes,

‘Ego’ is he who says ‘ego’. That is where we see the foundation of ‘subjectivity’ which is determined by the linguistic status of ‘person’.

Consciousness of self is only possible if it is experienced by contrast. I use *I* only when I am speaking to someone who will be a *you* in my address (Benveniste, 1971: 225).

Because *I* is a linguistic sign – and therefore usable by the whole linguistic community – it cannot begin to represent the fullness of one human being’s self-consciousness. It is only a word. However, as relations in the linguistic sign are necessary, it invariably feels natural to humans that the word does have this power to represent.

In this light, it is easy to see how Benveniste so influenced post-structuralism. “It is in and through language that man constitutes himself as *subject*,” he writes, “because language alone establishes the concept of ‘ego’ in reality, in *its* reality which is that of being” (Benveniste, 1971: 224). For Benveniste, the separation of *I* and *you* in dialogue was crucial to the category of *person* because it is the means by which the individual sets himself or herself up as a subject in discourse. The personal pronouns are just one, albeit most important, means by which each speaker appropriates a language; deixis is another means, demanding that meaning can only be realized with reference to the instance of discourse in which the deictic category appears. As such, language creates the

designation of person; but it also contributes to the human understanding of such supposedly autonomous phenomena as time and space.

Benveniste recognizes in Saussure's theory of the sign a fundamental split that he extends to the realm of subjectivity. If the relations in the linguistic sign are 'arbitrary' when placed under analysis, but 'necessary' (felt to be natural and automatic) when used, it is possible that this indicates the subject of signs is pulled two ways. Benveniste identifies two sides of any use of language: he calls these *énoncé* and *énonciation*. The *énoncé* is simple enough: it is the statement or content of the particular instance of language, what is being said. The *énonciation*, on the other hand, is the act of utterance and presupposes a speaker and a listener. The two can be recognized when separated in this abstract way but, in practice, they are always entangled. The subject of this dynamic in linguistic signs is in a dilemma. There will be the rendering of himself or herself as a subject represented in the use of pronouns such as *I* (*énoncé*); but there will also be that other 'I' who does the rendering (*énonciation*). The dilemma, here, is made clear in such paradoxical constructions as *I am lying*, in which the subject speaking **must** be separate from the subject represented in the instance of discourse.

If Benveniste's furthering of Saussurean sign theory took place in relation to a theory of the subject, Louis Hjelmslev's contemporaneous co-opting of Saussure was more oriented to the extension of the system. A Danish linguist and member of the Copenhagen School of linguistics, Hjelmslev founded the post-Saussurean linguistics called glossematics. Effectively, glossematics extended Saussure's investigations into *la langue*, particularly the latter's insistence that this is a form and not a substance. Harris writes,

Glossematicians took the Saussurean dictum that *langue* is "form not substance" (Saussure, 1916: 163) to its logical conclusion, and argued that the languages now in existence and available to observation are merely historical realizations of certain systems that could equally well exist in other manifestations (not necessarily spoken and not necessarily written either). Thus "the task of the linguistic theoretician is not merely that of describing the actually present expression system, but of calculating what expression systems in general are possible as expression for a given content system, and vice versa" (Hjelmslev, 1970: 105) (Harris, 2001:128).

Whereas Hjelmslev had previously focused on distinctive features as elements of form in his early work, glossematics sought to identify systematic 'functioning' of signs. He embarked on an identification of signs in *langue* as, precisely, 'functions' in relation to 'functives.' A function exists, for example, between a

class and its components, a chain and its parts or a paradigm and its members (or between members or parts or components). A functive, on the other hand, is the 'terminal' – at either end – of a function.

Hjelmslev proceeds from the preliminary notions that language is a system of signs and that the sign – by virtue of its being for someone – must be construed as a function. However, he insists that the sign conceived in this way must be clarified as a 'sign-expression.' As such, then, there are two planes to be considered in the analysis of language as a sign system. The first is the 'expression plane,' which has both a form and a substance. The second is the 'content plane,' which has the same. Both are made up of a restricted number of non-sign entities, *figurae* (such as phonemes), which can combine to produce an unlimited number of signs. The fact that there are two planes of the sign means that, for Hjelmslev, the notion of the sign as simply for someone is limited. This view tends to see the sign as a matter of an indication by an 'expression' of some external 'content,' whereas the Saussurean view, according to Hjelmslev, sees the sign as generated by the connection between an expression and content. If the sign relation is seen as a function, however, the functives of expression and content can never be separable and this has consequences for the conception of the sign. Chiefly, Hjelmslev's work contends that the sign does not just indicate; rather it is made up of 'content substance' ordered into 'content form,' is juxtaposed for sign users with other examples of content form (e.g., *ring* might indicate both jewellery for the finger and something that emanates from the telephone), and is constituted also on the plane of expression as an 'expression form' (containing specifically organized *figurae*), which is itself ordered to an 'expression substance' (other pronunciations, other enunciations by other people, etc.).

Hjelmslev's glossematics thus instituted a procedure that treated all text elements as relations of function within expression and content. Yet, because the relation of function was seen by him as all important, and because both were made of ('meaningless') *figurae*, those elements that make up 'expression' and those that make up 'content' are to be considered interchangeable. It was the combination of Hjelmslev's resolute systematization and his facilitation of the mutability of planes according to function that made his glossematics so amenable to other structuralist linguists and thinkers.

The early work of Roland Barthes (1915–1980) marks him, perhaps, as heir to Hjelmslev as much as to Saussure. This is clear in some of Barthes formulations such as 'denotation,' 'connotation,'

and ‘metalanguage.’ However, ultimately, Barthes saw himself as furthering Saussure’s sign theory and, certainly, initiating Saussure’s vaunted project of a semiology, a science that studies the life of signs within society. Commentators tend to agree that Barthes’s work developed significantly enough during his career for there to be a manifest difference between the early and later Barthes. Usually, it is assumed that the earlier Barthes is a semiologist concerned with Saussure’s sign theory, while the later breaks with this. However, it is not too difficult to see extensions and continuities of Saussure from *Mythologies* (1957) to *S/Z* (1970). Barthes book of 1964, *Elements of semiology* (translated into English, 1967a), is particularly noteworthy because it purports to be both a treatise and a primer of Saussurean theory of the sign. Indeed, *Elements of semiology* has been, in many instances, almost taken as the word of Saussure rather than Barthes.

For Barthes in *Elements of semiology*, it is the repetition of signs in successive discourses that entails that each sign become an element of the language (*la langue*, “language without speech” [Barthes, 1967a: 14–15]). However, according to Saussure, *langue* is a heuristic means for thinking about the language system; language without speech would actually be impossible. Barthes was keen to explicate an understanding of language not as a collection of discrete signs but as an organizing principle of discursive fields. Such discursive fields would not be constituted by verbal signs (and their connections) alone. Barthes therefore draws attention to the fashion system, where signs work in a somewhat different way. For Barthes, the garment cannot be an instance of speech; rather, it is always “a systematized set of signs and rules: it is a language in a pure state” (Barthes, 1967a: 26). This is because “fashion clothes (as written about) are the language at the level of vestimentary communication and speech at the level of verbal communication” (Barthes, 1967a: 26). The feature of the sign that seems to be most crucial for Barthes and that encourages him to make the counterpoint to Saussure is the idea of the sign as part of an ‘ideological’ organizing principle. Whereas individual or collective uses of speech (or individual or collective usages of food, the analogous example he uses; Barthes, 1967a: 28) might become part of language (or alimentary language) as a result of repetition or evolution, what makes up the constituents of ‘language’ in the case of fashion is the highly directed work of a ‘deciding group.’

Elements of semiology makes it apparent that central to his theory of the sign is the way that it can be not simply an ideological vehicle but, in fact,

ideological through and through. This is apparent in his comments on the nature of the *signifiant* and the *signifié* (usually translated into English, potentially confusingly, as ‘signifier’ and ‘signified’). Nevertheless, Barthes’s formulations in this area are the subject of some questions regarding their consistency and their Saussurean credentials. One reason for this is suggested by Roy Harris: that Barthes came to Saussure relatively late and that his understanding of the Saussurean sign was already refracted through the lens of his reading of Lévi-Strauss, Lacan, Jakobson, Martinet, Benveniste and, as noted above, Hjelmslev (Harris, 2003: 136). In respect of the latter, Barthes introduces accurate definitions of the *signifiant* and *signifié*, for example, but immediately reframes their operation in terms of form, substance, plane of expression, and plane of content (cf. Hjelmslev, 1970).

Barthes is initially very clear about the *signifiant* and *signifié*: they are an acoustic image and a mental concept, respectively. He underlines the latter, in fact, by writing “the signified [*signifié*] is not a thing but a mental representation of the thing” (Barthes, 1967a: 42). However, Harris points out that while Barthes’s formulations about the internal relations in the sign are unexceptional, his definition of what the sign (*signe*) is, concentrating on the relation between *signifiant* and *signifié*, misses its mark. For Harris, Barthes

fails to see that for Saussure the *signe* is indeed not only a linguistic unit but *the* linguistic unit, and not a mere ‘rapport’ between its constituent parts. *A fortiori*, the fundamental Saussurean tenet that in *la langue* semiological relations take priority over – and determine – units sinks without trace in Barthes’ exposition ... Barthes had not only missed the most original theoretical feature of Saussure’s account of linguistic structure, but reinstated precisely the concept that Saussure was at pains to reject, i.e., the sign as a mere correlation between antecedently given items (formal and semantic) (Harris, 2003: 141).

Yet Barthes’ placing of the sign before the semiological relations of *la langue* has a further twist that has been undoubtedly influential and has served to distort the picture for those who take the account in *Elements of semiology* to be the definitive exposition of Saussure. In drawing attention to the “nature of the signifier [*signifiant*],” Barthes writes that

it is purely a *relatum*, whose definition cannot be separated from that of the signified [*signifié*]. The only difference is that the signifier is a mediator: some matter is necessary to it. But on the one hand it is not sufficient to it, and on the other, in semiology, the signifier can, too, be relayed by a certain matter: that of the word. This materiality of the signifier makes it once more necessary

to distinguish clearly 'matter' from 'substance': a substance can be immaterial (in the case of the substance of the content); therefore, all one can say is that the substance of the signifier is always material (sounds, objects, images) (Barthes, 1967a: 47).

It is fairly clear why Barthes makes this un-Saussurean assertion about the *signifiant* and, indeed, he is not shy about it:

In semiology, where we shall have to deal with mixed systems in which different kinds of matter are involved (sound and image, object and writing, etc.), it may be appropriate to collect together all the signs, *inasmuch as they are borne by one and the same matter*, under the concept of the *typical sign*: the verbal sign, the graphic sign, the iconic sign, the gestural sign are all typical signs (1967a: 47).

For Barthes, the business of establishing a semiology in which verbal and nonverbal signs can be considered equally leads him to override Saussure's fundamental principle in which the relations within the linguistic sign are purely mental. This is probably the most characteristic feature of Barthes's theory of the sign, although, unfortunately, the fact that *Elements of semiology* has often been treated as a faithful explication of Saussure rather than as a manifesto, has prompted the erroneous belief that Saussure's *signifiant* is the same as Barthes' (see, for example, Bignell, 1997; Cobley, 1996).

Another feature of Barthes' revision of Saussure concerns the vaunted 'arbitrariness' of relations in the sign and, here, Barthes takes his cue from Benveniste and then Martinet. In respect of the word *ox*, Barthes suggests, after Benveniste, that the relation of *signifiant* and *signifié* "is by no means arbitrary (for no French person is free to modify it), indeed, it is, on the contrary, necessary" (Barthes, 1967a: 50). Ultimately, however, Barthes suggests that the relation is one that is determined by different degrees of 'motivation.' An unmotivated system, he argues, is one where signs are not founded by convention but by unilateral decision; so, for him, signs in *la langue* are not unmotivated but signs in the world of fashion (where there is an elite organizing body) are. Signs are motivated, on the other hand, when the relation between *signifiant* and *signifié* is analogical (Barthes, 1967a: 51). This is evidence of Barthes' attempt to smooth the transition from Saussure's linguistic sign to a general semiology containing, for example, pictorial signs whose *signifiant/signifié* relation is, frequently and unavoidably, one of motivation.

It is evidently important for Barthes that there be an analytic unity in his theory of both verbal and nonverbal signs, chiefly because the ravages of

ideology, when exposed, would be less convincing if they were distributed unevenly across different kinds of signifying system. Indeed, Barthes' justly famous essays on photography (1977a, 1977b) are important in this respect since they indicate that the denotative sign enacts a motivated relationship often as if it were in the service of 'validating' the injustice of the connotative sign, establishing its literalness and helping to ground ideology. Barthes's close analytic readings, many of them informed by an implicit use of Saussure's notion of syntagmatic-paradigmatic interaction, have informed the practice of students of media, culture, and communications to the present day, although the later work of Barthes is often assumed to transcend Saussurean sign theory as though his earlier work did not. In a later book, *S/Z* (Barthes, 1970), Barthes does consider signs from a slightly different angle. However, one could argue that this work still struggles with the vicissitudes of the Saussurean sign.

In the opening pages of *S/Z*, Barthes formulate two kinds of texts, the 'readerly' and the 'writerly,' where the reader is respectively an idle consumer of the signs in the text or a diligent producer of it, almost rewriting what is presented (Barthes, 1974: 3–4). Barthes goes so far as to actively advocate the latter position but, curiously, the intense analysis that follows these comments and makes up the majority of the book produces an implicitly conflicting conclusion. *S/Z* dissects a Balzac short story, 'Sarrasine,' dividing it up into very brief segments and by elaborating five codes through whose matrix the text passes. The result is to expose an abundance of meanings, making a text that might have been billed as a 'simple realist narrative' into one that now threatens to be eminently 'writerly.' It is not clear whether Barthes set out to demonstrate that 'realist' texts – exemplified by 'Sarrasine' – somehow carried signs that purported to possess a 'stable,' one-to-one *signifiant/signifié* relationship. Yet, if this was Barthes's intention, then it is clear that the final delivery of *S/Z* stymied it. The Saussurean version of the sign was by no means complicit with 'readerly' texts; indeed, the analysis might suggest that post-Structuralist versions of the sign were not guaranteed to produce 'writerly' texts.

If one feature of Barthes's analyses has been an extension of Saussurean sign theory to make it almost synonymous with the analysis of everyday phenomena (as opposed to an element in the understanding of linguistic systems), then his work is of a piece with that of the enormously influential structuralist anthropologist, Claude Lévi-Strauss (b. 1908). To be sure, Lévi-Strauss was heavily influenced by a

number of thinkers (Marx, Kant, Durkheim, Mauss, Jakobson) but most prominent among these, perhaps, was Saussure. Lévi-Strauss's work until the mid-20th century focused on kinship systems and marriage rules, while later he concentrated on belief systems embodied in myths and religion. Inspired by phonology, Lévi-Strauss had developed a methodology to investigate marriage alliances and myth. Yet, more specifically, crucial to Lévi-Strauss's conception of anthropology was Saussure's insistence on how the differentiability between linguistic signs gives rise to value (*valeur*).

Rather than carrying intrinsic 'meaning,' Saussure argued that linguistic terms were imbued with an identity that relied totally on their difference to other terms. For Lévi-Strauss, in turn, differentiability characterized a range of anthropological phenomena, particularly in the practices of exchange to be found in kinship rules, but also elsewhere. This included such binary formulations as the 'raw' and the 'cooked,' one of a number of anthropological oppositions discussed at length by Lévi-Strauss in a Saussurean spirit heavily refracted through the work of Jakobson and Troubetzkoy. Taking the oppositions instanced by phonemes as the smallest possible units participating in the differentiability of language, Lévi-Strauss proceeded to formulate both a study of myth and of 'savage' thought in general. The analogy of phonemes combining and opposing to produce linguistic signs that might be employed in systems of exchange informed, for example, his analysis of kinship.

In his theory of myth, Lévi-Strauss considered mythic narratives to rely on 'mythemes' – a term that directly echoes 'phonemes,' of course. The conclusions that Lévi-Strauss reached about Saussure – that "language can be analyzed into things which are at the same time similar yet different" (Lévi-Strauss, 1977: 209) – encouraged him to concentrate on the 'form' by which phonemes were combined rather than the strictly semantic orientations of a myth's content. Lévi-Strauss thus devised a method that enabled him to break down all myths to allow the identification of a basic substrate. The most famous example of this is his 1955 interpretation of the Oedipus myth in which he treats it "as an orchestra score would be if it were unwittingly considered as a unilinear series" (Lévi-Strauss, 1977: 213).

Say, for instance, we were confronted with a sequence of the type: 1, 2, 4, 7, 8, 1, 3, 4, 6, 8, 1, 4, 5, 7, 8, 1, 2, 5, 7, 3, 4, 5, 6, 8 ... the assignment being put to all the 1s together, all the 2s, the 3s, the result is a chart:

1	2		4			7	8
		2	3	4		6	8
1				4	5		7
1	2				5		7
			3	4	5	6	8

(Lévi-Strauss, 1977: 213)

He then goes on to break down the features of the Oedipus myth – for example, 'Oedipus marries his mother, Jocasta' and 'Antigone buries her brother, Polynices, despite prohibition' (Lévi-Strauss, 1977: 214) – which he reorders in a similar way. Effectively, Lévi-Strauss comes up with four columns of relations in the myth: (a) overrating of blood relations; (b) underrating of blood relations; (c) slaying of monsters; (d) (names for) difficulty of balance/standing. These mythemes suggest that the orchestrated myth has at its core a common human concern: anxiety over our origins. Put another way, the myth plays out the drama of humankind's quest to determine whether it has been forged in blood/earth or by human reproduction.

In the face of post-structuralism's revisions of his theoretical position and, in particular, the critique leveled by Jacques Derrida, Lévi-Strauss remained an unrepentant reductionist, revealing in his work the *langue* behind copious examples of *parole*. Lévi-Strauss was not alone in proposing such broad formulae at this time. In a series of articles in the late 1950s and early 1960s, which culminated in the 1966 book, *Sémantique structurale*, A. J. Greimas (1917–1992) worked out a semiotic project influenced by Hjelmslev and Saussure. Considering myth and narrative, Greimas, in a fashion that, from a distance at least, seems akin to that of Lévi-Strauss, gave priority to structural relations between narrative entities rather than to their intrinsic qualities. Lévi-Strauss, along with Vladimir Propp (1895–1970) and Greimas, effectively gave birth to the discipline known as 'narratology.' Narratology is a specific way of understanding narrative that was developed out of Russian Formalism but relied to a large extent on the theory of the sign put forth by Saussure. Sometimes 'narratology' is the name given to any form of analysis of narrative, but this is misleading. The term, instead, refers to a particular period in the history of narrative analysis that has had important consequences for other areas of study but that has also, itself, been transformed by other disciplines and perspectives. What characterizes narratology most readily is a systematic, thorough, and disinterested approach to the mechanics of narrative – an approach that provides a stark contrast to those that observe or seek out 'value' in some narratives (and not others) or that provide hierarchies of narratives

based on spurious categories such as the 'genius' of an author or artiste.

Roland Barthes's essay 'Introduction to the structural analysis of narratives' (Barthes, 1977, [1966]) and Tzvetan Todorov's *Grammaire du Décaméron* (1969), the latter of which actually coined the term '*narratologie*,' represented the birth of narratology proper. In the late 1960s and early 1970s, these paved the way for works by names frequently associated with the narratological enterprise: Mieke Bal, Seymour Chatman, Dorrit Cohn, Gérard Genette, and Gerald Prince. The fundamental distinctions in narratology between, for example, 'plot,' 'story,' and 'narrative,' were, in different ways, developed by the immediate precursors of the main narratological enterprise who came after Russian Formalism. Both Propp and Lévi-Strauss undertake analyses of narrative that focus on 'story' or, in the latter's case, in an extension of the linguistic terminology from Saussure, 'semantic structure.' In *Morphology of the folktale* (originally published in Russian in 1928, then auspiciously translated into English in 1958, appearing in book form 10 years later), Propp analyzed 100 Russian folk stories. Rather than attending to the surface differences of the narratives, he examined their underlying commonalities, particularly the basic function of actions in each story. Propp identified 31 functions characterizing the tales: for example, 'One of the members of a family absents himself from home'; 'An interdiction is addressed to the hero'; 'The interdiction is violated'; through to 'The villain is punished' and 'The hero marries and ascends the throne.' Each of these functions is, of course, carried out by one or more of the *dramatis personae*. Propp therefore proceeded to isolate the seven basic roles of characters in his sample, listing the particular sphere of action to which each belonged: the hero, the villain, the princess (sought-for) and her father, the dispatcher, the donor, the helper, and the false hero.

As differential signs in narrative, which Propp named 'functions,' it was easy to see the connection between such elements and Saussurean sign theory as adjusted by Hjelmslev. It is in this frame that the categories introduced by Greimas were so influential. Most importantly, Greimas emphasizes the functional nature of Propp's *dramatis personae* by referring, instead, to 'actants.' 'Actants' or 'actantial roles' are defined in the following ways: in relation to each other, in relation to their place in the narrative's 'spheres of action' or 'functions,' and in relation to their place in the logic of a narrative. In Greimas's revision of the *dramatis personae* in *Structural*

semantics (1983, [1966]), the actants comprise 'subject vs. object,' 'sender vs. receiver' and 'helper vs. opponent,' a set of categories that replaces Propp's analysis based on character roles (heroes vs. sought-for person, father/dispatcher vs. hero, helper/provider vs. villain/false hero). Narrative meaning in this formulation is played out through the various functions: thus, the 'subject' searches for the 'object'; the 'sender' is on a quest, initiated by a 'subject' for an 'object'; and so on. In addition, Greimas explores the way in which the structure of narrative can be defined by the interaction of 'positive' and 'negative' functions such as the opposition between a relationship designated *A* and containing 'command/behest' (*a*) and 'acceptance' (*non a*), and a relationship designated *A* • consisting of 'violation' (*non a* •) and 'interdiction' (*a* •). Ultimately, the systematic scrutiny of these relations led Greimas to posit a 'semiotic square' of such coordinates as a tool for the analysis of narrative meaning.

The work of Greimas, as well that of many others, such as Barthes, had traveled a long way since adopting broadly Saussurean principles. Indeed, the extensions of Saussurean sign theory were often actually extrapolations from Saussure as explicated in the work of other linguists or cultural theorists. Another case in point is the sign theory of Jacques Lacan (1901–1981), which is heavily reliant on the work of Jakobson, Lévi-Strauss, and, especially, Benveniste. For Lacan as a psychoanalyst, the chief point about the linguistic sign was that it somehow misses something; it is unable to express the purely personal. This is because relations in the sign are arbitrary, allowing the same sign to be used by everybody else. In 1957, Lacan delivered a lecture at the Sorbonne entitled 'L'instance de la lettre dans l'inconscient ou la raison depuis Freud,' which incorporates a significant extension of Saussure's sign theory, while also pursuing a series of related questions evident in Lacan's work since the completion of his Ph.D. dissertation in 1932 (see Benvenuto and Kennedy, 1986: 107; Payne, 1993: 74).

Taking the fundamental constituent of the *Course in general linguistics*, Saussure's map of the sign with *signifié* on top of *signifiant* enclosed by an ellipse, Lacan inverts it and opens it up. He presents a picture of two identical doors distinguished only by the writing that appears above them (Figure 3).

Clearly, this is a version of Saussure's map (or algorithm) of the sign (Figure 4).

What is important here is that the priorities of Saussure are reversed by Lacan. The *signifié* (or mental concept) of what lies behind each door is

Figure 3 Lacan's twin doors. From Lacan, 1977.

Figure 4 Saussure's sign. From Saussure, 1983: 113.

determined entirely by the *signifiant* (what should be the 'sound pattern,' here, is translated without comment by Lacan into a written notation: 'Ladies,' 'Gentlemen') that lies above the door. A whole cultural law – as Lacan puts it, the subjection of public life to the law of urinary segregation – is engendered by the existence and location of the two *signifiants* as well as their difference from one another. Lacan seeks to demonstrate that the mental concept is created by the way in which language operates. So, in addition to inverting the priorities in the algorithm, Lacan also banishes the ellipse and reinforces the bar that separates *signifiant* and *signifié* to emphasize that there is an incessant possibility of the *signifié* sliding under the *signifiant*. The *signifiant* is therefore responsible for the birth of subjectivity; however, it does not give birth to the human as a whole. There remains in the human a complex domain of desires – the unconscious – ruled by an order that is totally different from that of the social institution, language.

The implications of Lacan's inversion of the Saussurean algorithm for the study of subjectivity are fairly clear. As such, his work was taken up in all manner of areas in the humanities. It was especially influential in film theory circles, particularly in the 1970s in Britain. Problematically, however, it was frequently seen as correcting the fundamentals of Saussure's sign theory (or, as was frequently the

case, misrepresenting his theory of the sign in order to carry out some fixing that was never needed in the first place) or, worse, seen as standing for the truth of the Saussurean sign. This is a pattern that can be seen in other Saussurean sign theory, especially in the Gallic tradition – for example, Derrida (1976: 27–73) and Baudrillard (1983) – but also as Saussurean sign theory was used as a central figure in other disciplines (see, for example, Coward and Ellis, 1977; Culler, 1975; Hall *et al.*, 1980; Dyer, 1982; Fiske, 1990; Bignell, 1997; Hall, 1997; Cobley, 1996). Yet there is one area of Saussurean sign theory which has been of utmost importance to its dissemination and must be briefly mentioned here.

In his indispensable volume on *Saussure and his interpreters* (2003), Roy Harris discusses the Students' Saussure, the Editors' Saussure, Bloomfield's Saussure, Hjelmslev's Saussure, Jakobson's Saussure, Lévi-Strauss's Saussure, Barthes's Saussure, Chomsky's Saussure, Derrida's Saussure, and History's Saussure. Implicitly discussed, but it could also have merited a chapter of its own, would be the translators' Saussure. The English translation of the *Cours* is interesting in itself and, indeed, as Harris himself produced the second translation of the *Cours* in 1983, modesty may have prevented him from discussing the issue in his volume. However, it should be noted that the first English translation of 1959 has damaged the understanding of the *Cours* and caused it to be falsely applied in various areas. One example from Wade Baskin's translation of 1959 will suffice to illustrate the problem. It is the rendering of *signifiant*, *signifié*, and *signe* as 'signifier', 'signified,' and 'sign.' The first of these items produced the major misunderstanding. In short, it gave the impression to English natives that the *signifiant* was anything that did the work of signifying or, to put it another way, a sign. This was precisely the formulation that Saussure wanted to avoid and Saussure is explicit about this on a number of occasions in the *Cours*. The term for the *signifié*, at the same time, seemed to imply anything that was the object of signification – that is to say, any **thing** that was being **signified**, whether that be a thing in the head or a thing in the world (with the implication that it was generally the latter). At a stroke, Saussure's psychological conception of the sign was lost and versions of semiology were given free rein to look at the whole panoply of cultural artifacts as if they embodied a *signifié/signifiant* relationship. In his 1983 translation, Harris did his best to regain some of the ground that had been lost by rendering *signifiant* and *signifié* as 'signal' and 'signification' in an attempt to give a more accurate flavor

of Saussure's sign theory and to head off erroneous extrapolations. However, the damage was already done and Harris' terms have not been widely taken up as yet. (Thus the present article retains the original French terms).

What is beyond doubt is that Saussure's theory of the sign has been extraordinarily influential and has generated some productive work while also spawning some monsters. The posthumous provenance of the *Cours* has, perhaps, entailed that the 'real Saussurean sign theory' will never be known. However, two points should be added. The theory of the sign in Saussure's *Cours* is still unfolding as new discoveries about the original Geneva course in general linguistics are made (see Harris, 2003: 214–252). And, while it may not be the word of Saussure himself, Saussure's *Cours* is still insufficiently read.

Scope and Binding: Semantic Aspects

A Szabolcsi, New York University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The scope of an expression *E* is the domain within which *E*'s interpretation can impact that of other expressions. In the simplest cases this domain coincides with *E*'s sister constituent (*E*'s syntactic scope). The reading where *E*₁ scopes over some *E*₂ is notated as *E*₁ > *E*₂. *E*₁'s impact on *E*₂ may be of different kinds. Some examples follow. In (1) teachers may vary with boys; similarly in (2) if scope is used to effect pronoun binding. In (3) negation eliminates existential import. In (4) the Grail need not exist in the actual world. In (5) the polarity item is licensed.

- (1) Every boy saw a teacher.
'every boy > a teacher'
- (2) Every boy saw the teacher who flunked him.
'every boy > him'
- (3) Nobody drew a circle.
'nobody > a circle'
- (4) Parsifal seeks the Grail.
'seek > the Grail'
- (5) You have not responded yet.
'not > yet'

(6) summarizes Montague's (1974) classical technique for obtaining a reading where *everyone* takes wide scope, binding *his* and inducing referential variation in *a picture*. *Every boy* is interpreted as a generalized quantifier (6b), and a property is formed from the interpretation of its scope (6c). Pictures may vary because they are chosen relative to individuals playing the subject role. Pronoun binding occurs due to the identification of two arguments.

- (6a) *Every boy showed his father a picture* [Reading 1] is true if and only if the property (6c) is an element of the set (6b).
- (6b) *every boy*: the set of properties every boy has
- (6c) *_showed his father a picture*: the property of being an individual such that there exists some picture or other such that this individual showed that picture to this individual's father

(7) restates the right-hand side of (6a) using a logical notation similar to Montague's. Going beyond first-order logic, lambda is the abstraction operator and *P* a second-order variable over properties.

- (7) $\lambda P \forall x [\text{boy}'(x) \rightarrow P(x)] (\lambda y \exists z [\text{picture}'(z) \wedge \text{showed}'(y, \text{father-of}'(y), z)])$

Although the operator-variable notation is widely used, it is semantically not essential. For variable-free

semantics, see Szabolcsi (1989), Hendriks (1993), Jacobson (1999), and Kruijff and Oehrle (2003).

The intended scope of an expression is often not its sister in the most straightforward constituent structure of the sentence. For example:

- (8a) *Every boy showed his father a picture* [Reading 2] is true if and only if the property in (8c) is an element of the set (8b).
- (8b) *a picture*: the set of properties some picture or other has
- (8c) *every boy showed his father _*: the property of being an individual such that every boy showed this individual to that boy's father

Discrepancies are often resolvable by using a storage mechanism (Cooper, 1983), by positing a more abstract syntactic structure called Logical Form (May, 1985), or by making surface structure more articulated (Kayne, 1998). In other cases substantial semantic considerations or even new interpretive techniques must be invoked.

One semantically significant case is scope independence, exemplified by branching and cumulative readings (Schein, 1993; Hintikka and Sandu, 1997; Landman, 2000):

- (9) Some relative of every townsman and some relative of every villager hate each other.
- (10) Less than five detectives solved more than six crimes between them.

The main topic of this article is scope dependency. Many of the semantic innovations are necessitated by the observation that different operators have different scoping and binding abilities (Szabolcsi, 1997a). Nominal and adverbial quantifiers are the best studied. At least three classes emerge: (unmodified) indefinites like *some girl*, *two girls*, distributive universals like *every girl*, and counting quantifiers like *more/less than three girls*. Existential scope and distributive scope are distinguished, and E-type anaphora and covariance with situations are added to traditional bound variable and coreferential readings.

Thus, contrary to the traditional view, scope and binding are not uniform and are not unanalyzable primitives, and the two do not always go hand in hand.

Differential behavior regarding binding was observed first. (All referential dependencies involving pronouns will be indicated by underlining.) Indefinites, but not universals or counting quantifiers, support cross-sentential anaphora. Texts describing scenarios constitute an exception:

- (11) A girl is laughing. She is happy.
- (12) Every girl is laughing. # She is happy.

(13) More than one girl is laughing. # She is happy.

(14) Every graduate steps forward. The dean shakes hands with him or her.

Indefinites also support sentence-internal anaphora outside their syntactic scope. On the relevant reading both *a donkey* and *it* are within the scope of *every*.

(15) Every farmer who owns a donkey beats it.

These two binding peculiarities inspired varieties of dynamic semantics (Hintikka and Sandu, 1997; Heim, 1982; Kamp and Reyle, 1993; Groenendijk and Stokhof, 1991), in which indefinites are associated with referents that outlive the indefinite's syntactic scope. Alternatively, "donkey pronouns" are interpreted as definite descriptions (Evans, 1980; Neale, 1990), and donkey anaphora may be reinterpreted using situation semantics (Heim, 1990; Elbourne, 2001):

(15') 'every farmer who owns a donkey beats the donkey(s) he owns'

(15'') 'every minimal situation containing a farmer and a donkey he owns extends to one where the farmer beats the donkey'

Büring (2004) extends "situation binding" to other cases where a quantifier binds a pronoun it does not c-command:

(16) Every boy's mother likes him.

(17) Some person from every city likes it.

Indefinites are also special in that their scope within the sentence may escape the containing clause or even island:

(18) Every boy made up a story in which two girls had a bad dream.
'there are two girls such that every boy made up a story in which they had a bad dream'

But such extra-wide scope of indefinites only pertains to their ability to remain referentially independent of higher operators. Like universals and counters, plural indefinites cannot induce referential dependency in higher material. Boys cannot vary with girls in either (19) or (20). Only bad dreams can.

(19) Some boy or other made up a story in which every girl/less than three girls had a bad dream.

* 'for every girl/less than three girls there is a possibly different boy who ...'

(20) Some boy or other made up a story in which two girls had a bad dream.

* 'for each of two girls there is a possibly different boy who ...'

This duality cannot be expressed in traditional terms. It necessitates a distinction between existential scope, potentially unbounded, and distributive scope, typically limited to the smallest tensed clause (Beghelli *et al.*, 1997; Reinhart, 1997). Wide existential scope is attributed to referentiality (Fodor and Sag, 1982) or to the existential closure of a choice function variable (Egli and von Stechow, 1995; Reinhart, 1997). A choice function looks at sets and chooses one element or subset of each. According to Reinhart, the determiner in indefinites is interpreted as a choice function variable, whereas the numeral is a cardinality marker. *O_{choice} two girls* picks out a set of two girls. Distributivity, if present, is due to the interpretation of the clausemate predicate, e.g., [*each*] *had a bad dream*.

Extra-wide scoping indefinites may nevertheless be referentially dependent:

(21) Every professor praised every student who reviewed a certain book (that he wrote).
'every professor > a certain book > every student'

Such dependencies have been attributed to intermediate existential closure or to an overt or understood bound pronoun in a maximal-scope indefinite (Skolemized choice functions) (Kratzer, 1998).

Clause-internally, all quantifiers can take existential and distributive scope over material they c-command. Whether inverse scope is possible at all is subject to cross-linguistic variation, and which quantifiers take inverse scope over which others depends on their syntactic hierarchy; therefore these matters are to some extent syntactic. But the classes of quantifiers that behave differently are semantically characterizable (Beghelli and Stowell, 1997; Szabolcsi, 1997b).

Both unmodified indefinites and definites pick out sets undergoing existential closure. As expected from the foregoing discussion, in (22) it is easy to keep the poems fixed (wide existential scope). But triplets of girls only marginally vary with poems, probably because predicates only marginally support inverse distributivity.

(22) Three girls know two poems/these poems/all the poems.

Universals like *every/each girl* readily take inverse distributive scope:

(23) Three girls know each/every poem.

Counting quantifiers may be intersective (*at least n ...*, *more/less than n ...*) or proportional (*few ...*).

They do not take inverse scope over universals (24) but they can make higher counters dependent (25):

(24) Every girl knows more/less than three/few poems.

(25) At least one girl knows more than three poems.

It is usually assumed that both universals and counters operate in the manner of generalized quantifiers, see (6b), and the distributivity of universals comes from lexical semantics. Hungarian presents evidence to the contrary. In that language, different types of quantifiers occupy different surface syntactic positions. Interestingly, the comparative quantifier *több, mint n* ... 'more than n ...' may occur either in the position of universals or in the position of counters. In the former case its interpretation is necessarily distributive; in the latter case it may be collective. This suggests that the former position has a distributive operator associated with it. *Every girl* is distributive because it only occurs in that position; its own contribution to interpretation is just the set of girls. This set plays a similar role as the one contributed by *two girls*. Counters may be the only quantifiers that truly operate in the manner of (6b). (Bare plurals on the existential reading are not regarded as quantifiers but as kind-denoters or as incorporated predicates.)

Semantic Value

J Dever, University of Texas, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

A total theory of linguistic understanding is often taken to require three subtheories: a syntactic theory, a semantic theory, and a pragmatic theory. The semantic theory occupies an intermediary role – it takes as input structures generated by the syntax, assigns to those structures meanings, and then passes those meanings on to the pragmatics, which characterizes the conversational impact of those meanings. Semantic theories thus seek to explain phenomena such as truth conditions of and inferential relations among sentences/utterances, anaphoric relations among terms, and ambiguity and incoherence of expressions.

One way in which a semantic theory can provide the required explanations is by associating each expression provided by the syntax with a particular entity called its semantic value. These semantic values then serve both to ground the desired semantic explanations and to provide the pragmatic theory with input material on which to operate. While almost any approach to semantic theorizing can be reified into a theory of semantic value – a Davidsonian truth-theoretic account, for example, can associate atomic expressions with axioms and complex expressions with derivations; a translational theory can associate expressions with expressions in the target language of translation – setting semantic theory in the context of semantic value is most typical of an approach to semantics running through Frege, Carnap, and Montague. This discussion begins with the relatively simple theory of semantic values found in Frege, and progresses through various complications of that basic formula. First, the Fregean framework is extended to a full semantic type hierarchy. Second, the Fregean use of truth as the foundational semantic value is expanded to a notion of indexed truth as the foundational semantic value is expanded to a notion of indexed truth suitable for intensional and context-sensitive languages. Finally, dynamic semantic theories are considered, which diverge from traditional semantic theories by using qualities other than truth to construct semantic values.

Writing in 1891, Frege in ‘Function and concept’ considers the function $x^2 = 1$ formed by abstracting from an expression such as $(-1)^2 = 1$. Observing that the result of replacing x by various arguments is sometimes a true equation and sometimes a false equation, he says:

I now say: ‘the value of our function is a truth-value [*Wahrheitswert*],’ and distinguish between the

truth-values of what is true and what is false. I call the first, for short, the True; and the second, the False (Frege, 1997: 137).

Frege’s shift from the adjectives ‘true’ and ‘false’ to the neologicistic nominals ‘the True’ and ‘the False’ marks the beginning of semantic theorizing grounded in semantic values. ‘*Wahrheitswert*’ then crosses into English as ‘truth value’ in Russell’s commentary on Frege in 1903 in *The principles of mathematics*, and the contemporary ‘semantic value’ appears to derive from this usage.

Frege’s semantic theory associates with each expression in the language a referent (*Bedeutung*). The various referents are then the semantic values of the expressions in the language. Two central theses governing Frege’s conception of semantic value can be identified:

1. The two fundamental types of semantic values are truth values and objects (the referents of singular terms). Other semantic values are derived from the fundamental types through the construction of functions. Call this the categorical principle. Frege recognizes the derived categories of (a) first-level n -ary functions from objects and truth values to objects or truth values (paradigmatically, predicates and truth-functional connectives) and (b) second-order n -ary functions from first-order n -ary functions to objects or truth values (paradigmatically, quantifiers and definite descriptors).
2. Semantic values of complex expressions are derived from semantic values of their composite expressions, typically (although not necessarily) via functional application of one semantic value to another. Call this the compositional principle.

A standard semantic theory for quantified first-order logic can be formulated in Fregean terms by assigning to predicates the characteristic functions of their extensions, to connectives functions from truth values to truth values, and to quantifiers functions from predicate-assigned functions to truth values. The resulting theory will, as desired, account for truth conditions of and inferential connections between sentences. Thus, for example, semantic values can be assigned as follows:

- The predicate ‘ F ’ interpreted as *is French*, is assigned the function f from objects to truth values such that $f(x)$ is the True if and only if x is French.
- The connective ‘ \vee ,’ interpreted as *or*, is assigned the function g from pairs of truth value to truth values such that $g(x, y)$ is the True if and only if at least

one of x and y is the True. The connective ‘ \neg ,’ interpreted as *not*, is assigned the function h from truth values to truth values such that $h(x)$ is the True if and only if x is the False.

- The quantifier ‘ \exists ,’ interpreted as *something*, is assigned the function j such that $j(x)$ is the True if and only if x is a function from objects to truth values, which does not map every object to the False.

From these semantic values, it can be determined that $\exists xFx$ is true if and only if something is French, and that $\exists x(Fx \vee \neg Fx)$ is a logical truth.

The basic Fregean framework of semantic values coupled with the categorical and compositional principles then generalizes in three significant directions in later semantic work. First, the space of semantic values is extended to a full type hierarchy based on truth values and objects. The roots of this extension can be seen in Tarski’s (1933) paper ‘The concept of truth in formalized languages,’ but the full implementation of the thought in semantic theorizing about natural languages occurs with Montague’s ‘The proper treatment of quantification in ordinary English’ and Lewis’s ‘Generalized semantics.’ Introductory treatments can be found in Heim and Kratzer’s *Semantics and generative grammar* and in the Dowty *et al.*’s (1980) *Introduction to Montague semantics*.

In Montagovian semantics, a categorical grammar is linked with a type hierarchy of semantic values. The categorical grammar takes a small collection of primitive syntactic categories. Ajdukiewicz’s work introducing categorical grammars in ‘Syntactic connexion’ uses N (name) and S (sentence) as the primitive categories. Derived categories are then defined as follows:

- $\langle \alpha/\beta \rangle$ = the category of expressions combining with a β -category expression to form an α -category expression.

Thus:

- Intransitive verbs can be of category $\langle S/N \rangle$. ‘Snores’ can combine with an expression of category N (‘Socrates’) to form an expression of category S (‘Socrates snores’).
- Nouns can also be of category $\langle S/N \rangle$. ‘Linguist’ can combine with an expression of category N (‘Socrates’) to form an expression of category S (‘Socrates is a linguist’). Placement of nouns in $\langle S/N \rangle$ is somewhat syntactically forced and is influenced by the treatment of nouns as predicates in first-order logic; other versions of categorical grammar contain a third primitive category T of nouns.

- Modal operators can be of category $\langle S/S \rangle$. ‘Necessarily’ can combine with an expression of category S (‘Aristotle is fond of dogs’) to form an expression of category S (‘Necessarily, Aristotle is fond of dogs’).
- Quantified noun phrases can be of category $\langle S/\langle S/N \rangle \rangle$. ‘Some linguist’ can combine with an expression of category $\langle S/N \rangle$ (‘snores’) to form an expression of category S (‘Some linguist snores’).
- Determiners can be of category $\langle \langle S/\langle S/N \rangle \rangle / \langle S/N \rangle \rangle$. ‘Some’ can combine with an expression of category $\langle S/N \rangle$ (‘linguist’) to form an expression of category $\langle S/\langle S/N \rangle \rangle$, which in turn combines with an expression of category $\langle S/N \rangle$ (‘snores’) to form an expression of category S (‘Some linguist snores’).

The type hierarchy of semantic values similarly takes a small collection of primitive semantic categories. Following the Fregean tradition (and setting aside issues of intensionality to be raised below), the primitive categories can be t (the set of truth values) and e (the set of objects). Derived categories are then defined as follows:

$\langle \tau, \pi \rangle$ = the set of functions from category π to category τ .

If we then associate each syntactic category with a semantic category via a mapping $\llbracket \cdot \rrbracket$ such that:

1. $\llbracket N \rrbracket = e$
2. $\llbracket S \rrbracket = t$
3. $\llbracket \langle \alpha/\beta \rangle \rrbracket = \langle \llbracket \alpha \rrbracket / \llbracket \beta \rrbracket \rangle$

we can then obtain a semantic theory in which the semantic value of any complex expression results from the functional application of the semantic value of one of its immediate constituents to the semantic value of the other of its constituents. Both nouns and intransitive verbs, for example, are assigned functions from objects to truth values. Those functions can then be treated as characteristic functions determining predicate extensions.

This broadly Montagovian framework provides a fertile setting for much work in formal semantics. Barwise and Cooper’s (1980) work on generalized quantifiers, for example, fits naturally into such an approach. The categorical grammar yields the categories of $\langle \langle S/\langle S/N \rangle \rangle / \langle S/N \rangle \rangle$ for determiners and of $\langle S/\langle S/N \rangle \rangle$ for quantified noun phrases. The type hierarchy of semantic values then assigns values of type $\langle \langle t/\langle t/e \rangle \rangle / \langle t/e \rangle \rangle$ to determiners and of type $\langle t/\langle t/e \rangle \rangle$ to quantified noun phrases. ‘All philosophers’ for example, is assigned a function from extensions (in the form of

characteristic functions from objects to truth values) to truth values. The appropriate function is that which maps to the True sets that have the set of philosophers as a subset, and to the False other sets. The determiner 'all' then receives as semantic value a function from $\langle t/e \rangle$ values (predicate extensions) to quantified noun phrase values $\langle t/\langle t/e \rangle \rangle$. The appropriate function for 'all' is that which maps each set X of objects to the function that maps a set Y to the True if and only if $X \subseteq Y$. The type hierarchy yields a natural space of all possible quantifiers, allowing the location of semantic universals governing quantifiers in natural language, of the sort Barwise and Cooper set out. Thus, monotone increasing quantifiers, such as 'some linguist' and 'every mathematician,' are assigned functions f such that, for any extensions X and Y , if $f(X)$ is the True and $X \subseteq Y$, then $f(Y)$ is also the True. Monotone increasing quantifiers thus support inferences of the form:

Some linguist owns a red car. Therefore, some linguist owns a car.

in which the predicate of the conclusion is more restrictive than that of the premise. Monotone decreasing quantifiers, on the other hand, are assigned functions f such that, for any extensions X and Y , if $f(X)$ is the True and $Y \subseteq X$, then $f(Y)$ is also the True. Monotone decreasing quantifiers such as 'no archaeologist' and 'few physicists' support inferences of the form:

Few physicists own a red car. Therefore, few physicists own a car.

in which the predicate of the conclusion is less restrictive than that of the premise. Not all quantifiers are monotone in either direction, as examples like 'an even number of chemists' show – Barwise and Cooper thus hypothesize that all simple natural language quantifiers are conjunctions of monotone quantifiers.

Many complications of the simple type hierarchy of Montagovian semantics can now be investigated. Partee and Rooth's 'Generalized conjunction and type ambiguity,' for example, argues that expressions cannot be assigned a single stable semantic category. In the sentence:

John caught and ate a fish

the transitive verbs 'caught' and 'ate' need to be assigned the category $\langle \langle t/e \rangle / e \rangle$. If each transitive verb is assigned a function from entities (e) to intransitive verb extensions ($\langle t/e \rangle$), then their conjunction will be assigned the function that maps any entity x to the intransitive verb that assigns the True to any

entity that caught and ate x . This function can then combine with the entity assigned to 'John' to create an appropriate truth value for the whole sentence. However, this category assignment for transitive verbs fails in other examples such as:

John needed and bought a new coat.

The truth value of this sentence does not depend on a function that maps entities x to intransitive verbs assigning the True to entities that needed and bought x , since we do not here require that John needed and bought any one particular entity. Instead, we require that John needed and bought one type of entity. Thus, the transitive verbs 'needed' and 'caught' must be assigned the category $\langle \langle t/e \rangle / \langle t/\langle t/e \rangle \rangle \rangle$. By assigning to each transitive verb a function from nouns ($\langle t/e \rangle$) to truth values, their conjunction will then be assigned the function that assigns the True to any object that needed and bought that type of object. Partee and Rooth (2002) thus suggest that the semantic value assigned to an expression can undergo type raising, which moves it from a simpler to a more complex type to fit constructions such as these.

The second generalization of the core Fregean framework is the move to truth at a specification point. The first instance of this is the intensionalization of Frege's extensional logic. The roots of intensionalization can already be seen in Frege's separation of sense and reference in 'On sense and reference,' but the full picture emerges in Carnap's *Meaning and necessity*. Carnap introduces state descriptions – negation-complete sets of atomic sentences equivalent to possible worlds – and defines truth in a state description. He then assigns to every expression both an extension and an intension. Its extension is its semantic value in the Fregean truth value/object-based type hierarchy, and its intension is its semantic value in a parallel hierarchy based on functions from state descriptions to truth values and functions from state descriptions to objects. Given a designation of an extensionally privileged state description (the actual world), the extensional type hierarchy can be subsumed into the intensional. The intensional type hierarchy is connected conceptually to the Fregean type hierarchy via an understanding of truth at a world in terms of truth simpliciter (what would be true, were the world a certain way). This conceptual connection allows the intensional semantics still to address questions of truth conditions and inferential connections.

The basic insight of the intensionalizing move is that a finer-grained semantics can be achieved by replacing truth values simpliciter in the type hierarchy

with indexed truth values, in the form of functions from some set of indexes to truth values. The result is a semantic theory equipped for nontruth-functional operators such as modalities. A similar approach can thus accommodate tense by moving to truth at a time (or at a time/world pair). The same insight is employed in adapting the Fregean framework to context-sensitive expressions. Kaplan, in 'Demonstratives,' gives a semantic theory in which expressions are assigned intensions (both modal and temporal) with respect to a context, where a context provides information at least about utterance speaker, spatial and temporal location, and world. Kaplan's system thus uses a form of double-indexing; the background type hierarchy is grounded on functions from pairs of indices $\langle\langle\text{world}, \text{time}\rangle, \text{context}\rangle$ to truth values and objects. Thus, the sentence:

I am a philosopher

can be assigned a truth value only relative first to a context that determines the referent of the indexical 'I' and second to a world-time pair that determines the properties of the contextually provided referent. Kamp's approach to tense in 'Formal properties of now' uses a similar system of double indexing, and Stalnaker (1978) in 'Assertion' gives a streamlined version of the double-indexing approach, based on Segerberg's (1973) two-dimensional modal semantics, in which both indices are simply worlds.

Context-sensitive semantic theories thus extend the Fregean framework further in the direction begun by intensional semantics, by extending the indexing of truth at the foundation of the type hierarchy. The introduction of double-indexing gives rise to a novel issue in interpretation. The single-indexing of intensional semantics typically comes with a collection, in the analyzed language, of intentional operators that act on the indexing position; thus the expression 'necessarily' binds the world index in the semantic value of expressions it governs, causing them to be evaluated at every possible world. As a consequence, the new foundational semantic category of truth-at-an-index can be reductively understood via the simple truth of some claim containing an intensional operator. For example, a claim ϕ 's being true at a world w can be reduced to the intensionally modified claim 'If it were the case that w^* , it would be the case that ϕ 's being simply true' (where w^* is a canonical description of world w). However, in double-indexed semantic theories, the second indexed position is typically not subject to semantic interaction with intensional operators of the language. In a sentence such as:

I am always here.

the intensional operator 'always' controls the first index, governing the temporal evaluation of the verb. It does not, however, govern the second index, determining the contextual assignment of semantic values to 'I' and 'here.' Double-indexing thus means that truth at an index can no longer be understood in terms of what would be (or was, or will be) a true simpliciter. It requires instead a novel understanding of the elements of the type hierarchy. The result is the idea that semantic value characterized at a certain level ('utterance meaning') varies based on context of use, so that the same expression can have different semantic contents in different contexts of use.

The third and final generalization of the Fregean framework is the move to dynamic semantics. Dynamic semantics can be thought of as the other side of the coin of context sensitivity, investigating the way that expressions affect, as well as are affected by, context. Dynamic semantic theories have flourished over the last 25 years, taking such forms as discourse representation theory, file change semantics, dynamic predicate logic, and update semantics. When placed in a compositional form, one distinctive characteristic of dynamic semantic theories is a move away from indexed truth to a nontruth-based fundamental semantic value. Overviews of major topics in dynamic semantics can be found in Gamut's (1991) *Logic, language, and meaning* and in Kamp and Reyle's (1993) *From discourse to logic*.

Groenindijk and Stokhof's (1991) dynamic predicate logic, for example, makes dynamic the semantic analysis of sentences of first-order logic using sets of satisfying assignments to variables (where truth is equated with satisfaction by all assignments). In dynamic logic, a sentence is associated not with a static set of assignments, but with a function from input assignments to output assignments. An existential claim of the form ' $\exists x Fx$ ' pairs an incoming assignment g with an outgoing assignment h if and only if h satisfies Fx and there is some assignment $g \in G$ such that g and h differ at most in the x position. Quantifiers thus have unrestricted rightward scope; by passing on assignments whose x positions satisfy the existentially quantified matrix, future reference to and description of these objects is then possible. This unrestricted rightward scope allows dynamic predicate logic to model the behavior of crossclausal anaphora on indefinite noun phrases, as in:

A man walked in the park. He wore a hat.

The dynamic move to nontruth-based semantic values is more radical than the intensionalizing

move to semantic values based on truth at an index. One consequence is that associated semantic concepts require redefinition. Equivalence, for example, can no longer be understood as sameness of truth value in all models, in the absence of truth-based semantic values. Dynamic predicate logic allows multiple notions of equivalence, the stronger of which is identity of behavior in input–output conditions:

$\phi \simeq \psi$ if ϕ pairs an input assignment g with an output assignment h if and only if ψ does as well.

$\exists xFx \wedge Gx$ is not equivalent to $Gx \wedge \exists xFx$ in this sense, since an assignment g whose x position does not satisfy Gx will produce no output when input to $Gx \wedge \exists xFx$, but can produce an output when input to $\exists xFx \wedge Gx$, since in the latter case the x value can be ‘reset’ to an object satisfying F and G , if there is such an object. Similarly, dynamic predicate introduces a new consequence relation:

$\phi \models \psi$ if and only if for any model \mathcal{M} and any assignment g in \mathcal{M} , if the input of g to ϕ produces some output assignment h , then the input of h to ψ produces some further output assignment k .

The resulting consequence relation differs from classical consequence relations in many structural features. Idempotence fails; we do not have $Gx \wedge \exists xFx \models Gx \wedge \exists xFx$, since the output assignment, with its reset value in the x position, need not satisfy Gx . Transitivity similarly fails, since $\neg\neg\exists xFx \models \exists xFx$ and $\exists xFx \models Fx$, but $\neg\neg\exists xFx \not\models Fx$, since negation blocks dynamic effects.

Semantics of Interrogatives

B Sherman, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Many problems in semantics are typically expressed as problems about how to define a function from the form of a sentence to the conditions in which the sentence can be uttered truly (or, alternatively, to a proposition that can be expressed by an utterance of the sentence). The main problem posed by interrogatives for the truth-conditional approach to semantics is rather different. They do not give rise to a problem of how to map a function from the form of a sentence to its truth conditions. Rather, they give us reason to suspect that there is no such function. For interrogatives, unlike indicatives, do not seem to have truth conditions, and nor do they seem to express propositions that themselves have truth conditions. The main problem interrogatives pose is metasemantic: to say what a semantics for interrogatives must do.

In the 'Metasemantics' section of this article, I survey three attempts to deal with this question. In the 'Semantics' section, I present some basic-level semantic questions that would need to be addressed even if the metasemantic question were settled – though in all probability they will in fact **help** us to settle the metasemantic question.

Metasemantics

Above, I introduced one constraint on choosing a semantic framework for interrogatives: interrogative sentences are not true or false, so we should not assign to them some semantic object that is true or false, at least not without further explanation. Another is the Davidsonian constraint of 'semantic innocence': the fixed meaning of a word should not vary with the environment in which it occurs. This constraint generates a tension with any approach to the metasemantic problem that ignores the truth-conditional approach that works so nicely for indicative sentences. For this reason, the three dominant frameworks that I will focus on all treat the semantics of interrogatives in broadly truth-conditional terms. That is, in all of the frameworks to be discussed here, the meaning of an interrogative is in some way tied to a propositional object of some sort. In the rest of this section, I will look at the following three approaches to the metasemantic problem: the force/radical approach, the epistemic-imperative approach, and the question-as-answer approach.

According to the force/radical approach, sentences can be factored into two components: a force indicator and a propositional radical. Roughly, the

propositional radical supplies the truth-conditional content to the sentence, and the force indicator suggests the attitude taken toward that content. So, on this approach, advanced by McGinn (1977), Davidson (1984), and Stainton (1999), sentences (1) and (2) have the same radical and different moods:

- (1) The monkey is hungry.
- (2) Is the monkey hungry?

The mood of the sentence indicates the force of a typical utterance of the sentence. Sentences in the indicative mood are typically used for asserting the proposition expressed by the radical. Sentences in the interrogative mood are typically used to ask whether the proposition expressed by the radical is true.

This picture works well for yes/no questions, such as (2). What about wh-questions, such as (3)?

- (3) What does the monkey want?

The radical of (3) could be thought of as a propositional function of the form in (4):

- (4) λx : the monkey wants x

Some story would then be needed to explain why attaching an interrogative mood to (4) would yield the desired interpretation. In addition, it seems like the only mood one could attach to (4) is the interrogative mood. This seems out of character with the general approach, which emphasizes the possibility of attaching different moods to the same radical, thus requiring some explanation if the approach is to be defended.

The epistemic-imperative approach treats the meaning of an interrogative as an imperative concerning one's epistemic state. Sentence (2) would be analyzed as meaning what (5) means, and (3) would be analyzed as meaning what (6) means.

- (5) Let it be the case that (or: Bring it about that)
I know whether the monkey is hungry.
- (6) Let it be the case that (or: Bring it about that)
I know what the monkey wants.

On this approach, advocated by Åqvist (1965) and Hintikka (1983), the direct interrogative exemplified by (2) and (3) is analyzed in terms of the indirect interrogative contained in (5) and (6). In order for this approach to provide a semantic framework for interrogatives, an account of the semantics of indirect interrogatives is needed.

Hintikka gave an analysis of 'know whether' in terms of 'know that.' Sentence (5) on this analysis would be equivalent to (7):

- (7) Bring it about that either I know that the monkey is hungry, or I know that the monkey is not hungry.

However, this analysis of indirect interrogatives faces difficulties when embedded under verbs such as 'wonder':

- (8) I wonder whether the monkey is hungry.

Sentence (8) does not seem susceptible to a similar sort of paraphrase, causing trouble for any view that attempts to analyze away the indirect interrogative.

Finally, the question-as-answer approach treats the interrogative, either direct or indirect, as denoting a question, where this is understood to be a special sort of semantic object. Since a question determines a set of answers, the set of answers is used as a surrogate object for the question (much in the way that a set of possible worlds is used as a surrogate object for propositions). The intuitive idea motivating this approach, originating in Hamblin (1958), is that to know the meaning of a question is to know what counts as an answer to it. Different versions of the approach differ in which set of answers is used.

On the most standard version of this approach, advanced by Hamblin (1958) and Groenendijk and Stokhof (1994), the meaning of an interrogative should be thought of as the set of possible answers to a question, where this set of possible answers forms a partition of logical space. Every possible answer on this view is a complete answer to the question, and the set of answers jointly exhausts the possibilities of complete answers.

Karttunen (1977) provided two reasons for treating the meaning of an interrogative as the set of its true, rather than possible, answers. First, consider sentence (9):

- (9) Who is elected depends on who is running.

According to Karttunen, this sentence says that the true answer to the subject position question depends on the true answer to the object position question. So treating the meanings of interrogatives as sets of true answers provides a more straightforward account of verbs such as 'depend on.' Second, consider sentences (10) and (11):

- (10) John told Mary that Bill and Susan passed the test.

- (11) John told Mary who passed the test.

Sentence (11) entails that John told Mary the truth, whereas this is not the case with sentence (10). By treating the indirect interrogative in (11) as denoting a set of true answers, this entailment is straightforwardly explained.

Karttunen's account has some counterintuitive consequences, however. For example, somebody who asks question (2) in a situation where the monkey is hungry intuitively asks the same question as somebody who asks question (2) in a situation where the monkey is not hungry. But on Karttunen's account, the meaning of the questions asked in the two situations is different, since the true answers to the questions asked are different.

A more general worry with the question-as-answer approach, articulated by Stainton (1999), is that it makes the domain of the interrogative – the set of objects that figure in the possible answers to it – a part of its meaning. It seems intuitive that one can understand a question without knowing anything about the objects that figure in the possible answers to it. For example, if an alien from outer space lands on Earth, we might ask the question 'What does the alien want?' Surely, among the possible answers to this question are objects that we've never seen or imagined before. But that doesn't stop us from understanding the meaning of the question, as it seems it should on the question-as-answer approach.

Although the approaches to the metasemantic problem presented here are dominant in the literature, they are by no means exhaustive. Ultimately, the success of a given framework will depend on the extent to which it is successful in accounting for various semantic phenomena.

Semantics

One of the ongoing semantic debates in the semantics of interrogatives concerns the ambiguity that results from a *wh*-question containing a universal quantifier, as in (12):

- (12) Who does everyone like?

According to one reading of (12), the question is asking which people are such that every person likes them. An appropriate answer might be, for example, 'Bill and Mary.' On the other reading of (12), the question is asking which person each person likes. An appropriate answer to this question would be a list of pairs of people of the form 'Bill likes Mary, Mary likes Sue, Sue likes Bill.' The debate specifically concerns this second reading of the question, called the *pair/list* reading. The question is how to account for that reading semantically.

There have been two main sides to the debate. According to one standard view, the role of the quantifier that occurs in the interrogative is to restrict the domain of the question. So (12) could be paraphrased roughly as (13):

- (13) For every person, who does that person like?

Exactly how this paraphrased reading is derived from (12) will depend in large part on the metasemantic approach that one favors. For example, Groenendijk and Stokhof (1984) modified Karttunen's metasemantic approach in implementing their view.

According to an alternative view, pair/list readings are an instance of a more general kind of reading. Consider the following question/answer pair in (14):

- (14a) Who does every man love?

- (14b) His mother.

The answer in (14) gives rise to a functional reading of the question. The answer to the question is not an individual, but a function – that is, a rule which takes one from an object to another object. Pair/list readings are, according to this alternative, functional readings, where the function is specified extensionally, in terms of the ordered pairs in the extension of the function. This view was presented in Engdahl (1985) and developed by Chierchia (1993). Accounting for functional readings is an interesting semantic issue in its own right. For alternative accounts of pair/list readings, see Beghelli (1997), Szabolcsi (1997a), and Pafel (1999).

Another semantic issue concerns the nature of the presuppositions that different sorts of questions give rise to. For example, the question 'What is it like owning a monkey?' presupposes that the addressee owns a monkey. The question 'Who came to the party?' presupposes that someone came to the party. The question 'Which monkey ate the banana?' presupposes that a unique monkey ate the banana. Whether these presuppositions are semantic in nature and, if so, where they arise from has been a contested issue. See Belnap and Steel (1976), Karttunen (1977), Higginbotham and May (1981), and Hintikka (1983).

A final semantic issue that is of both linguistic and philosophical interest concerns the context sensitivity involved in whether something counts as an answer to a question. This issue is particularly pressing for the question-as-answer approach, since most versions of that approach assume that each question has some unique complete answer. Ginzburg (1995) developed a novel account of the semantics of interrogatives aimed at accommodating various sorts of context sensitivity. In general, questions calling for the identification of something seem to be interest relative. For example, the sentence 'Where am I?' might be used to ask for the country in which one is located, the street on which one is located, the room in which one is located, etc. In some situations, one counts as knowing who killed Lady Chittlesworth when one knows

simply that the murderer is the person that was wearing the yellow shirt. In other situations, this would not count as an acceptable answer. See Boër and Lycan (1985) for an account of knowing who someone is.

This brief survey of issues is far from exhaustive. For a very useful overview of both metasemantic approaches to interrogatives and semantic issues concerning interrogatives, see Groenendijk and Stokhof (1994).

Semantics–Pragmatics Boundary

The Philosophical Debate

Texts in the philosophy of language frequently cite the tripartite distinction between syntax, semantics, and pragmatics made by Morris (1938). According to Morris, syntax is concerned with the structural properties of signs (i.e., with word-word relations), semantics with the relations between signs and the things they signify (i.e., with word-world relations), and pragmatics with the uses of signs by speakers and hearers to perform communicative acts (i.e., with word-user relations).

Philosophers generally follow Frege in rejecting any form of mentalist semantics. They think of languages as “abstract semantic systems whereby symbols are associated with aspects of the world” (Lewis, 1972: 170). There is a potential infinity of both syntactically well-formed (grammatical) and semantically well-formed (meaningful) sentences in any language, and it is the job of semantics to identify rules that generate this potential infinity. On the other hand, since we are interested in the semantics of **natural** languages, these rules must be ones that are learnable by humans with finite minds. Semanticists are interested in what a competent speaker knows when she knows a language (i.e., her syntactic and semantic competence). Hence they assume that what a speaker knows is a **finite** set of rules that can compositionally generate the potential infinity of syntactically well-formed sentences and that can deliver a **semantic interpretation** for every meaningful sentence of the language.

Philosophers generally assume that there is a sharp division between syntax/semantics and pragmatics. While semantics studies the rules that a competent speaker knows when she knows the meanings of sentences, pragmatics studies how sentences are used in conversational contexts to communicate a speaker’s messages. Pragmatics is thus concerned with linguistic **performance** rather than competence. It is **by** using sentences with certain syntactic and semantic properties that speakers succeed in communicating certain things. So, the central question of pragmatics is how we succeed in our communicative tasks.

Many philosophers are convinced that Grice (1975, 1989) made an important start in answering this question by articulating his Cooperative Principle and maxims of conversation. Grice sees conversations as rational cooperative activities where hearers use

their linguistic knowledge, together with mutually available nonlinguistic contextual knowledge, to infer what the speaker means to communicate. The principles that guide conversations are analogous to the principles that guide any sort of rational cooperative activity, such as the joint activity of building a house or sailing a ship. Pragmatic principles on this view are not tied essentially to any language mechanism and are certainly not language-specific rules, unlike the syntactic and semantic rules that define a language.

An alternative view, argued for by Prince (1988, 1997), assumes that there are rules of use associating certain linguistic forms with certain functions. Moreover, these rules are language-specific, in the sense that the same pragmatic function could be served in different languages by different forms; so any competent speaker of the language must learn these rules. Knowledge of these rules constitutes the speaker’s pragmatic competence. Hence it is incorrect to put the study of pragmatics on the performance side of the competence/performance divide. Related to Prince’s ideas are those of Kasher (1991), who argues for a modular conception of pragmatics. Just as linguists have postulated a grammar module, so Kasher argues there is a module governing pragmatic processes, with its own proprietary rules and representations. Since it is Grice’s conception of pragmatics that has set the agenda for debate in the philosophy of language, these alternative views will be set aside here.

Gricean pragmatics introduces the idea that it is **by** saying certain things in certain contexts that speakers are able indirectly to communicate (to implicate) certain further things. In working out what a speaker has implicated, a hearer will use his knowledge of the conversational maxims, together with contextually available knowledge, to infer what the speaker communicated. For example, after a terrible ordeal in which a man is rescued from a remote mountainside after a plane crash, a TV reporter interviews him. The reporter asks: ‘Were you ever afraid?’ and the man replies: ‘I felt a twinge or two.’ By his understatement he has implicated that things were pretty bad. The understatement is a violation of Grice’s first Maxim of Quantity, which enjoins speakers to say as much as is required by the purposes of the talk exchange. The hearer, having recognized the violation, but assuming that the speaker is still bound by the Cooperative Principle, will search the context for further information that the speaker might have intended to convey. It is his background knowledge – of human psychology, of the probable consequences of plane wrecks, and of the low probability of survivors being found

in remote, sparsely populated places – that allows the reporter to infer the speaker's intended meaning.

The currently dominant view in philosophy of language is that a theory of meaning for a language specifies the truth-conditions for each of the sentences of a language. It does this by specifying a finite set of rules that compositionally generates these truth-conditions. This truth-conditional approach to semantics has been grafted onto a Gricean view of pragmatics. It is generally accepted that saying and implicating are neatly separated. Saying is tied to sentence meaning and the expression of truth-conditional content. What a speaker says when she utters a sentence (i.e., the locutionary content of her utterance) corresponds to the truth-conditional content of the sentence. (Note that the notion of **saying** is not to be conflated with the notion of **stating**. The former is a locutionary act, namely the act of expressing some content. The latter is an illocutionary act. It is the expressing of some content with a particular illocutionary force.) Implicating is tied to (indirectly or implicitly) communicated content that can be inferred once the hearer has figured out what the speaker has (directly or explicitly) said. Since truth-conditional content is the province of semantics and implicature is the province of pragmatics, the saying/implicating divide goes along with a neat divide between semantics and pragmatics. Consequently, many believe that truth-conditions can be specified in a way that is essentially free from pragmatic considerations.

But there are problems with this Gricean view. One of the first indications of trouble for this view came from some observations by Cohen (1971). Others, such as Carston (1988, 2002), Levinson (1995, 2000) and Recanati (1989, 2004) have used examples similar to Cohen's to challenge the Gricean picture. Consider examples such as the following:

- (1) Mary fell pregnant and she got married.
- (2) Mary got married and she fell pregnant.

Grice would say that (1) and (2) have the same truth-conditional content, but that they implicate different things. (1) implicates (in a generalized way) that the pregnancy occurred before the marriage, whereas (2) implicates the opposite. (1) also implicates that the reason for Mary's marriage was her pregnancy. However consider examples such as the following:

- (3) If Mary fell pregnant and she got married, her grandma will be shocked.
- (4) If Mary got married and she fell pregnant, her grandma will be shocked.

According to Grice, the antecedents of the two conditionals have the same truth-conditional content.

Therefore, (3) and (4) should themselves have the same truth-conditional content, yet intuitively they do not. (3) could be true while (4) is false. It looks as though the implicated content of (1) and (2) has become incorporated into the truth-conditional content of (3) and (4). In other words, (3) and (4) in effect express the following:

- (3') If Mary fell pregnant *and then for that reason* she got married, her grandma will be shocked.
- (4') If Mary got married *and then* she fell pregnant, her grandma will be shocked.

Clearly, (3') and (4') differ in content, so it is not a problem if one is true and the other is false.

These appear to be cases of pragmatic intrusion into truth-conditional content. Such pragmatic intrusion creates a problem for Grice that Levinson (2000) calls 'Grice's Circle.' The trouble is that to figure out what is conversationally implicated, the hearer must first determine what is said (since it is **by** saying such-and-such that a speaker succeeds in implicating something else). However, in figuring out what was said by (3) or (4), it looks as though one must first determine their implicated contents.

Levinson (1995, 2000) argues that pragmatic intrusion is not problematic, since it is limited to the intrusion of **generalized** conversational implicatures (GCIs), and these, he argues, are **default meanings** that will be automatically triggered by the use of certain kinds of expressions. The derivation of GCIs is governed by various heuristic principles. For example, the I-Principle can be summarized in the slogan 'What is simply described is stereotypically and specifically exemplified.' It applies only to 'unmarked, minimal expressions' (Levinson, 1995: 97). It enjoins speakers to minimize what they say when their hearers are able to use contextually accessible information to enrich the informational content of their utterances. Conversely, it enjoins hearers to amplify or enrich the informational content of the speaker's utterance up to the point that they judge is the speaker's intended meaning. Since 'and' is the sort of minimal, unmarked expression that calls for a stereotypical interpretation, conjunctions such as (1) and (2) will be given an interpretation according to which the events described by the two conjuncts are temporally ordered. The net effect is that (3) and (4) will be understood to express (3') and (4') respectively.

Not everyone would agree that in (3) and (4) we have pragmatic intrusion into truth-conditional content. Cohen (1971) appeals to examples of embedded conjunctions that seem to affect the truth-conditions of the larger sentences in which they are embedded to argue for a **semantic ambiguity** account of 'and.' If the suggestion of temporal ordering associated with

(1) affects the truth-conditions of (3), Cohen concludes that this feature must be part of the semantically encoded meaning of ‘and.’ Since relations other than temporal ordering can be suggested by a conjunction, this view is committed to a multiple ambiguity account of ‘and.’ In addition to conjunctions such as (1) and (2), consider examples such as:

- (5) It is summer in Europe and winter in Australia.
- (6) The fan turned on and {as a result} a cool breeze blew through the room.
- (7) Peter took a shower and {while in the shower} he practiced his singing.

In some cases, as in example (5), ‘and’ expresses simple truth-functional ‘and,’ and the conjuncts can be reversed without changing the meaning. In others, such as (6), it expresses a causal relation ‘and as a result,’ or, as in (7), a temporal containment relation ‘and while.’ In these last two cases, the relations are asymmetric, and reversing the conjuncts changes the meaning. For instance, reversing (6) suggests a different causal scenario, where the breeze somehow turns on the fan. Examples could be multiplied, and for each case where a different relation is suggested, Cohen would have to posit yet another meaning for ‘and.’

Carston (1988) and Recanati (1989) argue against positing a semantic ambiguity for ‘and,’ maintaining instead that the contents represented between brackets in the above examples are **pragmatically determined aspects of what is said**. (See entry on **Pragmatic Determinants of What Is Said**.) Rather than being semantically ambiguous, ‘and’ is **semantically underspecified**. It will be pragmatically enriched in different ways, depending on the assumptions that are operative in the conversational context.

Carston and Recanati agree with Levinson that there is pragmatic intrusion. However, they point to embedded contexts, like the conditionals (3) and (4), to argue that the pragmatic content associated with (1) and (2) belongs to what is said, rather than being conversationally implicated. (Carston (2002) prefers to use Sperber and Wilson’s (1986) technical term ‘explicature’ instead of the term ‘what is said,’ since the latter has a commonsense usage that interferes with attempts at terminological regimentation.) If the pragmatic content of a simple sentence has an effect on the truth-conditional content of the compound sentences in which it is embedded, then that pragmatic content is part of what is said by the simple sentence, not something that is merely implicated. Recanati calls this the Scope Test.

Other tests have been proposed for determining whether some pragmatically determined content is part of what is said. Recanati (1989) proposes his

Availability Principle, according to which any content that intuitively seems to affect truth-conditions should be regarded as a part of what is said. Carston (1988) proposes her Functional Independence Principle, which requires both explicatures and implicatures to occupy independent roles in inferential interactions with other assumptions. Take example (8) discussed below. The simple encoded content that Mary engaged in an act of swallowing is not functionally independent of the enriched content that Mary swallowed a bug. The latter entails the former, and it is from the latter that further contextual effects can be derived. This suggests that it is the enriched content that corresponds to what is said, not the more minimal encoded content, which has no autonomous role to play.

Explicatures are pragmatic developments of semantically encoded content and can be either **enrichments** or **loosenings** of encoded content. Carston argues that the processes involved in the recovery of explicatures are inferential processes and, hence, no different from the sorts of inferential processes involved in the derivation of conversational implicatures. What distinguish explicatures from implicatures are not the sorts of processes involved in their derivation but the starting points of these inferential processes. Derivations of explicatures begin with the semantically underspecified representations of logical form (LF) that are the output of processes of grammatical decoding. Implicatures, on the other hand, as Grice insisted, are contextual implications that follow from contexts including assumptions about what was said (i.e., including explicatures). This is **not** a commitment to the claim that explicatures are processed before implicatures. In fact, Carston thinks that the processing of explicatures and implicatures happens in parallel, and that the overall interpretation of a speaker’s utterance is something arrived at via a process of mutual adjustment.

Recanati, on the other hand, distinguishes local from global pragmatic processes. The sorts of processes involved in the derivation of pragmatic determinants of what is said are of the local sort and are noninferential. For instance, such local processes might involve spreading activation within an associative conceptual network, or the accessing of stereotypical information from conceptual frames or scripts. Such processing happens at a subconscious level, and only the output of such processes is consciously available. In contrast, global pragmatic processes are inferential processes of the sort that Grice claimed are involved in the derivation of conversational implicatures. Such inferential processing is in principle consciously available, in the sense that language users can become aware not just of the conclusions of such

reasoning but also of the inputs to such reasoning, as well as to the (putative) fact that premises and conclusions are inferentially connected.

Bach (1994) provides yet another perspective on these matters. Bach wishes to maintain a more minimalist conception of semantics and of what is said. Yet he acknowledges that there are pragmatically determined contents that are not Gricean implicatures. He introduces a third category of contents, intermediate between what is said and what is implicated, that he labels 'implicatures.' He regards these as contents that are implicit in what is said and that require pragmatic processes of either **completion** or **expansion** to be made explicit. Consider the following, where the content in brackets is supplied from contextually available information:

- (8) Mary swallowed {the bug that flew into her mouth}.
- (9) Mary invited everyone {in her department} to her wedding.

The sentence 'Mary swallowed' is syntactically and semantically complete. (Compare it to 'Mary ate,' which is syntactically but not semantically complete, since 'eat' is a two-place relation. Or to 'Mary devoured,' which is neither syntactically nor semantically complete, since 'to devour' subcategorizes for an obligatory second NP, and 'devour' has two semantic arguments). Bach regards (8) as an example of **conceptual** incompleteness, and hence a pragmatic process of completion must operate, resulting in the derivation of the implicature that Mary swallowed the bug that flew into her mouth.

On the other hand, 'Mary invited everyone to her wedding' expresses a complete proposition. Bach calls this a **minimal proposition**, since the domain of the quantifier is not restricted in any way (beyond the restriction to persons that is encoded by 'one' in 'everyone'). However, this minimal proposition is not the one that the speaker intends to communicate. A pragmatic process of expansion is required, yielding the implicature that Mary invited everyone in her department to her wedding. Bach calls examples such as (9) cases of **sentence nonliterality**. No expression in the sentence is used nonliterally, yet the minimal proposition expressed by the sentence is not what the speaker intends to convey.

Bach denies that there are pragmatically determined aspects of what is said. What is said for Bach is a more minimal notion, which is tied to explicitly encoded semantic content. Bach in effect accepts what Carston (1988) calls the Linguistic Direction Principle. The only contextually determined content that belongs to what is said by the utterance of a sentence is content that corresponds to some element that is

syntactically realized in that sentence. Thus the contextual values of the indexicals in 'She is swallowing now' will be part of what is said by an utterance of this sentence, but the implicit content that specifies what was swallowed (if anything) will not be a part of what is said, since that content corresponds to no element in the sentence. Bach's minimalism requires him to admit that on some occasions what a speaker says does not correspond to a complete proposition. Such is the case in example (8) above. In such cases Bach argues that what is said corresponds to a 'propositional radical,' a gappy object whose missing conceptual elements must be supplied by the context.

Each of the authors discussed above posits a different view of the boundary between semantics and pragmatics. According to Grice, sentence meaning, truth-conditional content, and what is said are all aligned and fall on the side of semantics, whereas implicatures fall on the side of pragmatics. Cohen basically preserves Grice's dichotomy. Cases that may seem to be pragmatic intrusions into truth-conditional content are instead incorporated into semantics. If there is a challenge to Grice it is simply that some phenomena that Grice would label as conversational implicatures are reanalyzed by Cohen as part of semantically encoded content, so that the domain of pragmatics shrinks.

Subsequent views can all in one way or another be seen to challenge Grice's neat dichotomy. Bach remains the most faithful to Grice, since on the whole he preserves the alignment of sentence meaning, truth-conditional content, and what is said on the side of semantics. Truth-conditional content may sometimes come apart from what is said, in those cases in which what is said is conceptually incomplete and hence does not correspond to a complete, truth-evaluable proposition. But when we have truth-conditional content, it is something that is delivered purely by semantics. However, Bach argues that Grice's view of what lies on the side of pragmatics is inadequate. The phenomena of semantic underspecification and sentence nonliterality require us to recognize a category of pragmatic content intermediate between what is said and what is implicated – the category of implicatures.

Levinson's (1995, 2000) views are also quite close to Grice's. He accepts that sentence meaning and what is said line up, and that these are semantic phenomena. However, he allows that there can be pragmatic intrusion into truth-conditional content, so this notion is not a purely semantic notion. On the other hand, Levinson's conception of pragmatics is conservative. He does not challenge the adequacy of the Gricean conception of pragmatics as the domain of conversational implicatures. He does,

however, develop Grice's notion of a generalized conversational implicature (GCI) to a substantial degree. GCIs are said to be default meanings, which belong to a third level of meaning that Levinson calls utterance-level meaning, different from either sentence meaning or speaker meaning. It is only GCIs that are involved in pragmatic intrusion.

Carston's and Recanati's challenges to Grice are more radical. For them, the only purely semantic notion is sentence or expression meaning. What is said (which is equated with truth-conditional content) falls on the side of pragmatics, since there is pragmatic intrusion into truth-conditional content. (Remember, Carston prefers the term 'explicature'.) Carston (2002) suggests that we make a distinction between lexical and truth-conditional semantics. Lexical semantics studies those aspects of meaning that have some sort of syntactic reflex in the language and hence that are a part of the mental lexicon. The lexicon is a store of words in long-term memory. An entry in the mental lexicon is in effect a rule correlating the phonological, syntactic, and semantic information associated with a word. Lexical semantics on this conception is a mentalist enterprise. We can continue to talk of truth-conditional semantics, so long as we realize that the project is very different from the traditional one. Truth-conditions are not assigned directly to the sentences of a language, since sentences by themselves do not have truth-conditions. It is only sentences as used by speakers in particular conversational contexts that have truth-conditions. For a defense of a similar claim, see Stainton (2000).

Moreover, both Carston and Recanati reject Gricean pragmatics as inadequate, since for them pragmatics is not confined to the study of conversational implicatures. Recanati's rejection of Gricean pragmatics may be the most thoroughgoing, since for him, the pragmatic processes involved in the recovery of what is said are not even of the same type as the global pragmatic processes involved in the recovery of implicatures. They are noninferential processes.

Many other voices have been added to this debate. For example, Stainton (1995) argues for the view that semantic underspecification and pragmatic intrusion is rife. He points to the fact that many utterances are of sentence fragments, rather than of complete sentences. Consider:

(10) Top shelf.

Suppose Mary is making herself a sandwich and is rooting around in the kitchen cupboard looking for jam to spread on her toast, and that this is mutually manifest to Mary and her husband Peter. Peter could

utter sentence fragment (10), meaning to convey the proposition that the jam that Mary is looking for is on the top shelf of the cupboard she is searching in. Stainton argues that cases such as these are not to be treated as cases of ellipsis. The missing content in (10) need not correspond to any well-defined syntactic element, as happens in standard cases of syntactic ellipsis, such as the VP-ellipsis in 'Mary donated blood and so did Peter.' (Ellipsis is a very vexed subject. Whether it is something that can be handled in the syntax is not at all clear. See Jackendoff, 1997: 75–78, for a discussion of some problematic cases.) We should accept that language understanding is able to proceed on the basis of fragmentary clues from semantically decoded content. A large burden is placed on the inferential capacities of hearers, who must elaborate these clues on the basis of contextually available information.

Stanley (2002) argues for a diametrically opposed view. According to Stanley, there is much more syntactic and semantic structure than meets the eye, and many of the alleged cases of semantic underdetermination calling for pragmatic enrichment can be re-analyzed as cases where some hidden element in the underlying sentential structure is directing the process of content retrieval. In other words, we preserve the idea of the linguistic direction of content, although the elements doing the directing are often hidden elements (ones that are not phonetically realized, although they are a part of underlying logical form).

Stanley's views have been especially influential in accounting for cases of quantifier domain restriction, such as (9) above or (11) below:

(11) Every child has been vaccinated against polio.

(12) In every country, every child has been vaccinated against polio.

It is possible to use (11) in an appropriate context to convey the proposition that every child **in the United States** has been vaccinated against polio. Stanley's view is that there must be a hidden free variable in (11) whose value is specified in that context as the United States. This variable is present in the underlying logical form of (11) but is not phonetically realized. (Strictly speaking, what is implicit is a free **function** variable, and what must be specified in context is both the function and the values of the arguments of this function. In (11) the function is something like 'resident-in(x).') The evidence that there is a hidden free variable in (11) is that this variable can sometimes be bound by a quantifier. For example, when (11) is embedded in a sentence with a quantifier that has wide scope over the embedded quantifier, as is the case in (12), what is said is that in every country *x*, every child *in x* has been

vaccinated. For more detailed arguments, both pro and con, see Stanley and Szabó (2000), Bach (2000) and Neale (2000). This hidden indexical view has consequences for the quantificational analysis of definite descriptions and has led to some controversy as to the correct analysis of so-called incomplete descriptions. See the chapters in Part I of Reimer & Bezuidenhout (2004).

The Mentalist Picture of the Semantics-Pragmatics Boundary

It was noted above that many philosophers follow Frege in rejecting mentalist semantics. Many linguists on the other hand embrace mentalism, and in fact regard it as the only sensible perspective from which to study language. See Chomsky (2000), Jackendoff (1997, 2002). From the point of view of mentalism, the dispute about the semantics-pragmatics boundary is not one about how to delineate the notions of explicature, implicature, etc. Rather, it is concerned with the question as to how semantic and pragmatic knowledge are represented and organized in the human mind/brain and how this information is combined in the course of on-line production and comprehension of language. Several of the authors discussed above straddle the divide between philosophy and linguistics. Carston, for instance, works in the mentalist tradition. She is concerned to offer a mentalist theory of language **performance**. (So the suggestion made at the outset that semantics is concerned with competence and pragmatics with performance is one that Carston would reject.) On the other hand, although she is interested in articulating a cognitive theory of performance, she has also been an active contributor to the philosophical debate about how to delineate what is said from what is conversationally implied.

Within the mentalist framework, the dominant picture of the semantics-pragmatics interface has been that it is the interface between the language system proper and what Chomsky (1995) calls the conceptual-intentional system. From the comprehension perspective, this interface is where the output from the hearer's language system, namely a representation of the logical form (LF) of the speaker's utterance, is interpreted by processing it in the context of currently active pragmatic information, including information about the speaker's likely communicative intentions. From the production perspective, this interface is where the process of giving expression to a speaker's communicative intentions is initiated. Appropriate lexical-conceptual entries in the speaker's mental lexicon are accessed, thus initiating a process that will ultimately result in the output

of an appropriate phonetic form (PF) at the interface between the language system and the articulatory system.

Jackendoff (1997, 2002) challenges this Chomskyan view while remaining within the mentalist camp. He argues that the language system has a tripartite parallel architecture. There are three independent generative systems or modules, the phonological system, the syntactic system, and the conceptual system. Each contains its own compositional rules and proprietary set of representations, of, respectively, phonological structure (PS), syntactic structure (SS), and conceptual structure (CS). However, it is necessary for these systems to communicate with one another, and they do this via various interface modules, whose job it is to map representations from one system into the representations of another. There is a PS-SS interface, an SS-CS interface (which Jackendoff calls the syntax-semantics interface), and a PS-CS interface. The lexicon is also an interface module, and the interfaces already mentioned are in effect parts of this larger interface system. The lexicon is a long-term memory store whose entries are triples of the three sorts of structures mentioned, namely of PS, SS, and CS. The lexical entry for expression α , $\langle PS_\alpha, SS_\alpha, CS_\alpha \rangle$, is in essence a correspondence rule mapping representations from the three systems into each other. (Lexical entries may be for words, for phrases, such as idioms, or for expressions below the word level, such as agreement markers.)

What Jackendoff calls the syntax-semantics interface (namely the SS-CS interface) is of relevance to the current discussion, since he justifies his claim that CS is the level of semantics, and that it is a level separate from syntax, by appeal to phenomena of the sort that Carston, Recanati, and others appeal to in arguing for pragmatic intrusion into what is said (i.e., into the proposition expressed by an utterance). Jackendoff (1997) argues for what he calls enriched semantic composition. At the level of CS, the compositional principles that form propositions (or thoughts) are sensitive to information that comes from the pragmatic context. But not all this conceptual structure is reflected in the corresponding syntactic structures. Consider the following:

- (13) Peter kept crossing the street.
- (14) Mary finished the book.
- (15) The ham sandwich wants his check.

(13) illustrates the process of aspectual coercion, (14) of co-composition, and (15) of pragmatic transfer. See Pustejovsky (1995) for an account of the first two processes and Nunberg (1979) for an account of the third.

A single act of crossing the street is not a repetitive and (potentially) open-ended action like clapping one's hands or bouncing or spinning a ball. But 'kept' requires such repetitiveness and/or open-endedness. Thus, in the case of (13), 'kept' coerces an interpretation of 'crossing the street' according to which there is either a repeated or an extended action. That is, either we understand Peter to have crossed the street multiple times, perhaps in his effort to lose the detective tailing him. Alternatively, we zoom in on Peter's action of crossing the street and see it as one whose end point is still in Peter's future. Perhaps the street is a very broad one, with a median strip, where Peter pauses briefly before continuing with his crossing.

In the case of (14), finishing is something that can be predicated of an event, but 'the book' refers to an object, not an event. Pustejovsky (1995) argues that the lexical-conceptual entry for 'book' contains information about the typical features of books, namely that they have authors, are read by readers, etc. This conceptual information, presumably along with other contextual information, can be used to arrive at an enriched interpretation of (14) according to which Mary finished reading (or writing, or binding, or illustrating, etc.) the book. In the case of (15), contextual knowledge about restaurants and what goes on in them is used to arrive at an interpretation according to which the ham sandwich orderer wants his check.

In all these cases Jackendoff argues that there is more conceptual (semantic) structure than is represented syntactically. Some will be inclined to argue that there must be covert syntactic structure to match the semantic structure – structure that is there but is not phonetically realized. But Jackendoff argues that this is a mistake. Those who argue for covert structure are in the grip of an assumption that he calls syntactocentrism, namely the view that the only source of compositional structure is syntax. This is an assumption he attributes to Chomsky, since it is built into all the theories of the organization of the language system that Chomsky has proposed, from the Standard Theory of the 1960s, through the extended and revised versions of the Standard Theory in the 1970s, to the Government and Binding (GB) approach of the early 1980s and the minimalist approach of the 1990s. But Jackendoff's account of the tripartite parallel architecture of the language system rejects this assumption.

Moreover, Jackendoff goes further and argues that it is a mistake to talk of **any** semantic structure being directly encoded in the syntax, as Chomsky seems to suggest when he introduces the level of logical form (LF) and talks of it as the level in syntax that directly represents meaning (Chomsky, 1986: 68). It is unnecessary and perhaps even incoherent to talk

in this way. First, it is unnecessary, since the correspondence rules belonging to the syntax-semantics interface (the SS-CS interface) will do the work of correlating syntactic and semantic structures. Note also that the correspondence doesn't have to be perfect. There may be only a partial homology between these two systems. If the communicative system as a whole works in such a way that semantic structure is recoverable from readily available contextual knowledge, then the fact that some of this structure is invisible to the syntactic system is no bad thing.

Second, talk of semantic structure being encoded in syntax may be incoherent if that is allowed to mean that semantic distinctions are directly represented in the syntactic system. The syntactic system is a module whose internal operations are defined over representations in its own proprietary code. So the syntactic system knows about nouns and verbs, case markings, active and passive constructions, WH-movement, etc., not about objects and events, predicate-argument structure, the telic/atelic distinction, thematic roles, etc. Thus it could not represent the sort of pragmatic knowledge needed to interpret examples such as (13)–(15).

As already mentioned, Carston accepts Chomsky's picture, including the assumption of syntactocentrism. She holds that the output from the language system is a representation of LF, which includes those semantic features that are directly syntactically encoded. Earlier we saw her acceptance of the idea that lexical semantics is the study of such encoded aspects of meaning. So, for her, the SS-CS interface would be better called the semantics-pragmatics interface, not the syntax-semantics interface. This makes it seem that her views are very far from those of Jackendoff. Yet Carston's notion of pragmatic enrichment and Jackendoff's notion of enriched composition are very similar.

Jackendoff (2002: 273) does briefly allude to what he might call the semantics-pragmatics interface. It turns out to be an interface level between two sub-levels **within** the conceptual system. It is the level that integrates thoughts that are conveyed by means of language with one's previous knowledge, including knowledge of the communicative context and the speaker's intentions. Such integration may lead one to inferentially derive further thoughts (i.e., Gricean implicatures). In other words, Jackendoff's conception is basically the Gricean conception that is rejected by Carston, since it confines pragmatics to the derivation of implicatures, whereas Carston thinks pragmatic processes are also involved in the enrichment of lexical concepts (encoded meanings) to arrive at ad hoc concepts (contextualized meanings). Of course, Jackendoff can use terminology in the way

he pleases. However, to make it clearer that his views are in fact very close to those of Carston, it might be more appropriate to relabel Jackendoff's SS-CS interface the syntax-pragmatics interface.

This does of course still leave some disagreements unsettled. In particular, it leaves unsettled the issue of syntactocentricism and the debate as to whether there is a specifically linguistic part of semantics, separate from nonlinguistic knowledge, thought, and contextualized meaning. (See Jackendoff, 2002: 281–293, for reasons to deny that there is any such level of semantics.)

Sense and Reference: Philosophical Aspects

The Origins and Central Core of the Sense/Reference Distinction

In his earliest works (e.g., Frege [1879]), Frege espoused a referentialist approach to language, according to which the meaning of an expression is whatever it is to which the expression refers. The referentialist picture is simple and compelling: singular terms such as 'Nancy' mean objects, general terms such as 'doctor' mean sets or properties, and the meaning of a sentence such as 'Nancy is a doctor' is the fact or state of affairs that the sentence is about.

Informative identity statements – i.e., true but non-trivial statements of the form ' $a = b$ ' – shattered this picture for Frege. His classic example is

- (1) Hesperus is Phosphorus.

According to the lore, the Evening Star (the brightest heavenly body visible in the evening at certain times of the year) was baptized 'Hesperus,' whereas the Morning Star (the brightest body in the dawn sky at certain times) was baptized 'Phosphorus.' With the growth of astronomical knowledge, it turns out that Hesperus *is* Phosphorus, and what is more it is not a star at all but the planet Venus. The problem is to account for the difference between the meanings of (1) and

- (2) Hesperus is Hesperus.

As (1) and (2) are constructed from co-referential parts, the referentialist approach seems to be committed to the view that they say exactly the same thing. However, according to Frege, there are substantive differences here: " $a = a$ ' and ' $a = b$ ' are obviously statements of differing cognitive value; ' $a = a$ ' holds *a priori* ... while statements of the form ' $a = b$ ' often contain very valuable extensions of our knowledge and cannot always be established *a priori*" (1892: 175). Because referentialism cannot account for this evident fact about meaning, it is untenable, and a new view is wanted.

Frege's problem, then, is this: insofar as the function of a term is just to single out its referent, there is no way to distinguish the meanings of co-referential terms, and so no way to distinguish the propositions expressed by sentences that differ only in the interchange of co-referential terms. Frege's solution is that the semantic contribution of a term encompasses

more than just its referent. 'Sense' is the name for the dimension along which the semantic contributions of co-referential terms can differ. Every term is associated with a sense, and the sense specifies the condition for being the term's referent. Co-referential expressions can have distinct senses, and expressions need not have an actual concrete referent to have a sense.

The distinction between sense and reference is clearly illustrated in the case of a definite description, such as 'the tallest woman in Mongolia' or 'the architect who designed this building.' The sense is the identifying condition expressed by the term. It is that which must be grasped in order to understand the expression, and it is accessible to any competent speaker, regardless of whether they have been to Mongolia or seen this building. The referent is the individual that satisfies the condition that the sense specifies. Frege (1892) characterizes the sense as the mode of presentation of the referent. There are multiple ways of describing and conveying information about one and the same referent; and to each of these ways corresponds a distinct sense.

Frege's distinction generalizes well beyond cases like (1) and (2) – it is not limited to identity statements, or to singular terms. For example, (3) and (4) might differ in meaning, and (5) and (6) in truth-value, despite differing only in the interchange of co-referential terms:

- (3) Hesperus is visible in the evening.
- (4) Phosphorus is visible in the evening.
- (5) The ancient Babylonians believed that Hesperus is visible in the evening.
- (6) The ancient Babylonians believed that Phosphorus is visible in the evening.

Some related points are illustrated by sentences such as:

- (7) Pegasus does not exist.

Such negative existential statements with non-denoting names in the subject-position pose problems for referentialism, as (7) is clearly meaningful despite the fact that its subject-expression does not refer to any actual thing. Furthermore, the same points apply to general terms. For example, to be a renate, one must have kidneys, whereas to be a cordate, one must have a heart. All and only renates are cordates, so the terms are co-referential; nonetheless, they clearly differ in meaning, and so are subject to the phenomena illustrated by (1)–(6). There are also non-denoting

general terms – the term ‘phlogiston’, for instance, was introduced to name a substance given off in the process of fire. With the growth of knowledge, it turns out that there is no such thing, and so (8) poses problems for referentialism similar to those posed by (7):

(8) Phlogiston does not exist.

Frege concludes that, in general, the semantic contribution of an expression is not simply its referent. Instead, every significant linguistic expression has associated with it a sense that determines its referent. So, Frege’s distinction amounts to a fully general approach to language that posits an intermediate layer of sense between words and referents.

More on Frege’s Distinction

Frege’s approach to the word-referent relation is a classic instance of what is called ‘mediated’ or ‘indirect’ reference – reference is *indirect* because there is a sense *mediating* the link between a term and its referent. The characteristic virtue of the indirect reference approach is that it affords a clear semantic distinction between co-referential expressions.

The distinction between sense and reference is a distinction between what we say and what we say it about. The sense of an expression is its contribution to the content of the thought or proposition expressed by uses of sentences in which it figures; the referent of an expression is its contribution to the truth-value of this thought or proposition. To illustrate, when enjoying a work of fiction, we are only engaged at the level of sense – “The thought [expressed by a sentence in the *Odyssey*] remains the same whether ‘Odysseus’ has a reference or not” (1892: 180). However, if we are interested in whether a thought is true, then we become engaged at the level of reference. “The question of truth would cause us to abandon aesthetic delight for an attitude of scientific investigation. ... It is the striving for truth that drives us always to advance from the sense to the reference” (1892: 180). At the limiting case of a complete sentence, Frege takes its sense to be a thought or proposition, and its referent to be a truth-value (see Frege [1891, 1892] for further explanation).

Frege’s individuates senses in terms of cognitive significance. Two statements differ in cognitive significance if it is possible for a competent speaker to take contrasting attitudes toward them (i.e., to believe that one is true while disbelieving, or withholding judgment concerning, the second). According to Frege, pairs such as (1)–(2) and (3)–(4) differ in cognitive significance. If two statements that differ only in

the interchange of co-referential terms differ in cognitive significance, this proves that the terms differ in sense.

Consider again (3)–(6). Even though (3) and (4) differ in cognitive significance, they are nonetheless truth-conditionally equivalent, because they are built from co-referential parts. How then can (5) and (6) differ in truth-value, if truth-conditions are solely a matter of referents, not senses? Here Frege (1892) argues that in certain contexts (such as inside the scope of ‘A believes that ...’) the referent of an expression is its customary sense. (5) and (6) assert relations between agents and thoughts, not between agents and truth-values. They attribute distinct thoughts to the Babylonians, and thus can differ in truth-value.

Sense is that which links belief, meaning, and rational action. One might, for instance, believe that Hesperus is populated by an advanced and benevolent race and desire above all else to visit them, but still turn down a free trip to Phosphorus – and not be in the least bit irrational – as long as one does not believe that Hesperus is Phosphorus. Thus, senses are integral to the task of explaining and predicting rational action. Relatedly, merely identifying the referents of the expressions uttered is not sufficient for understanding what a speaker has said, on a Fregean view. (For instance, if one says ‘Hesperus is Phosphorus,’ to report or translate this utterance as saying that Hesperus is Hesperus is clearly unsatisfactory, even though it preserves truth-conditions.) To understand what has been expressed, one also needs to bear in mind the speaker’s perspective on those referents.

Subsequent History, and Criticisms

Frege’s distinction between sense and reference has had enormous impact on the subsequent development of the philosophy of language. Starting with Russell (1905), and continuing through seminal work by Davidson (1967), Kripke (1972), Putnam (1975), and Kaplan (1977), theorists begin their constructive projects by situating their theories in relation to Frege’s. Furthermore, the influence of Frege’s distinction is far from exclusively negative. There is a rich tradition, running through such influential theorists as Carnap (1947), Church (1951), and Montague (1974), which follows Frege’s indirect reference approach in assigning two such semantic entities to every significant linguistic expression. Down this path, Frege’s distinction had a direct influence on the development of more or less every single branch of intensional logic and semantics.

More generally, Frege's distinction is now pervasive throughout philosophy, a part of the canon. Whether the topic be ontology, minds, or morals, in any case in which it is important to bear in mind subtle distinctions between conceptual conditions and that which satisfies those conditions, one is likely to encounter the sense/reference distinction. (This is clearly illustrated in recent philosophy of mind, in which finessing the distinction between the sense and the reference of psychological [qualitative, phenomenal] terms is – interestingly, and tellingly – a core part of the arguments of both dualists [cf. Chalmers (1996)] and the physicalists who oppose them [cf. Papineau (2002)].)

There are, however, many critical questions raised by Frege's distinction between sense and reference. For one thing, positing senses gives rise to difficult metaphysical questions, such as: 'What, exactly, are senses?' Frege (1892, 1918) gives arguments about what senses are not – because co-referential expressions can differ in sense, senses are not of the physical realm; since distinct mental states can have exactly the same sense, senses are not private mental entities. However, as for what senses are, exactly, Frege (1918) just offers a vague metaphor: senses exist in some third realm, distinct from the physical and mental realms. Understandably, many find this 'third realm' talk to be beyond belief. At best, it is in need of significant clarification.

Some of the most influential objections to Frege's distinction were raised in the 1970s – led by Donnellan (1970), Kripke (1972), Putnam (1975), and Kaplan (1977). One way to put their basic thrust is this: two central constraints on senses are that they be answerable to concerns of cognitive significance and that they be objective; however, there is something subjective, or speaker-relative, about cognitive significance. (For example, two competent speakers could disagree as to whether it is significant or trivial to be told that Homer is the author of the *Odyssey*; and it is not evident that there are any objective grounds that would conclusively resolve such a dispute.) Thus, these two constraints pull in opposite directions, and it is not clear that any one thing can satisfy them both. More generally, the aforementioned articles give reasons to be skeptical as to whether expressions have one determinate objective sense, and, even if so, reasons to be skeptical as to whether this sense determines reference.

Led by Dummett (1981), Evans (1982), and McDowell (1986), neo-Fregeans have sought to defend refined interpretations of Frege's doctrines from some of these objections. (One of the core ideas is that many criticisms of Frege's views can be met if senses are conceived as object-dependent – and so

'rigid,' in Kripke's [1972] terminology.) In the other direction, original criticisms of Frege's approach continue to surface. (For an important example, see Schiffer's [1992] argument that nothing can satisfy the demands that Frege places on the notion of 'sense'.) In any case, it is evident that Frege's problem does pose a challenge to many views of meaning and reference, and that there is some aspect of meaning, distinct from reference, that is essential to understanding rational thought and intentional action. Exactly what Frege's problem shows, or exactly how to characterize the latter aspect of meaning, though, are complex matters that remain controversial.

Situation Semantics

V Akman, Bilkent University, Ankara, Turkey

© 2006 Elsevier Ltd. All rights reserved.

Situation theory starts with a fundamental observation: reality consists of situations. A situation is a rich object consisting of individuals enjoying various properties and standing in a variety of relations. It is, in a sense, a 'small' world. We always find ourselves in situations. Right now, you, the reader, are in a reading situation. You are, I hope, satisfied with your being in this situation (notice that this is an attitude you have toward this situation). Some months ago, I, the author of this article, was in a writing situation (distributed over time and place).

Situations describe parts of the real world. Information flow is made possible by a network of abstract links between high-order uniformities, that is situation types. One of the distinguishing characteristics of situation theory *vis-à-vis* the traditional account is that information content is invariably context-dependent (Akman and Surav, 1997).

Situation semantics is applied situation theory. We are engaged in situation semantics if we are using situation-theoretic ideas – mathematical theories of information content – to study meaning in natural language. In fact, the two areas are not clearly separable, as the still-popular acronym STASS (situation theory and situation semantics) neatly shows.

Unlike the older and widely known approaches to natural language meaning (e.g., Montague grammar), there is certain natural feel to situation semantics. This makes it enticing for a newcomer to the realm of semantics. Situation semantics does not impose human-made assumptions in our conceptual scheme. It may be burdensome for someone to embrace, say, Montagovian intensions, but situations have a certain conceptual clarity and naturalness that make them believable. You may have heard that the classical model theory is a 'model' theory in the sense that it depicts how a logical theory should be like. Likewise, situation semantics is a fine exemplar of what a naturalized theory of semantics should be like.

Classical approaches to semantics underestimate the role played by context; they ignore factors such as intentions and circumstances of the individuals involved in the communicative process. (Or, rather, they place them in the pragmatics basket.) But, linguistic devices such as indexicals, demonstratives, and tenses rely heavily on context for interpretation and are fundamental to the way language carries information. Context-dependence is essential to situation semantics. (The insistence of situation semantics on contextual interpretation makes it compatible with speech act theory and discourse pragmatics.) A sentence can be used over and over again in different situations to say different things (called the efficiency of language). Its interpretation (i.e., the class of situations described by the sentence) is therefore subordinate to the situation in which the sentence is used. This context-providing situation (discourse situation) is the speech situation, including the speaker, the addressee, the time and place of the utterance, and the expression uttered. Because speakers are always in different situations, having different causal connections to the world and different information, the information conveyed by an utterance will be relative to its speaker and hearer (called the perspectival relativity of language).

Context supports not only facts about speakers, addressees, and so on, but also facts about the relations of discourse participants to other contextually relevant situations such as resource situations. Imagine two card games that are going on, one across town from the other. Suppose Alice is playing rummy with Bob and Carol is playing rummy with David. Elwood, watching the former card game, mistakes Alice for Carol, and mutters, *Carol has the ace of clubs*. According to the classical theory, if Carol indeed has the ace of clubs (A♣), his claim would be true since *Carol* and *the ace of clubs* are used to pick, among all the things in the world, the unique objects satisfying the properties of being someone named Carol and being an A♣, respectively. In contrast, situation semantics identifies these objects with respect to some limited situation – the resource situation exploited by Elwood. The claim would then be wrong even if Carol had the A♣ in the other card game.

In traditional semantics, statements that are true in the same models convey the same information. Situation semantics takes the view that logically equivalent sentences need not have the same subject matter because they need not describe situations involving the same objects and properties. The notion of partiality leads to a more fine-grained notion of information content and a stronger notion of logical consequence that does not lose track of the subject matter.

Ambiguity is another aspect of the efficiency of language. Natural language expressions may have more than one meaning. There are factors such as intonation, gesture, the place of an utterance, and so on that may play key roles in the interpretation of an utterance. Instead of downgrading ambiguity as an impurity of natural languages, situation semantics tries to build it into a full-fledged theory of linguistic meaning.

Intelligent agents generally make their way in the world by being able to pick up certain information from a situation, process it, and react accordingly. Being in a situation, such an agent has information about the situations he or she sees, hears about, believes in, and so on. Thus, upon hearing Bob's utterance *a wolf is running toward you*, Alice would have the information that her friend is the speaker and that he is addressing her with *you*. Moreover, by relying on the situation the utterance described, she would know that there is a wolf fast approaching her. She would then form a thought about this – an abstract object having the property of being a running wolf – and, on seeing the wolf around, her thought would start to correspond with facts. Normally, the realization of some type of situation causes an agent to acquire more information about that situation and to act accordingly. Alice would run away, having in her possession the acquired knowledge that wolves are hazardous. She activates this knowledge from the situation she finds herself in via a constraint – the link between wolves and their fame as life-threatening creatures. The role of constraints in information flow is best illustrated with an example. The statement *smoke means fire* expresses the lawlike relation that links situations in which there is smoke to situations in which there is a fire. If s is the type of smoky situations and f is the type of fire situations, then, by being attuned to the constraint $s \Rightarrow f$, an agent can pick up the information that there is a fire in a particular situation by observing that there is smoke.

Meaningful expressions are used to convey information not only about the external world but also about our minds (called the mental significance of language). Returning to an earlier example, consider

the sentence *a wolf is running toward you* uttered by Bob. It can give Alice information about two different situations. The first one is the situation that she is located in. The second one is Bob's mental (belief) situation. If Alice is certain that he is hallucinating, then she learns the second situation, not the first. Situation semantics differs from other approaches in that in attitude reports we do not describe our mind directly (by referring to states of mind, ideas, senses, thoughts, and whatnot) but indirectly (by referring to situations that are external).

According to situation semantics, the meanings of expressions reside in systematic relations between different types of situations. They can be identified with relations on discourse situations d , (speaker) connections c , the utterance situation u itself, and the described situation e . Some public facts about u – such as its speaker and time of utterance – are determined by the discourse situations. The ties of the mental states of the speaker and the hearer with the world constitute c .

A discourse situation d involves the expression uttered, its speaker, the spatiotemporal location of the utterance, and the addressee. Each of these defines a linguistic role (the role of the speaker, the role of the addressee, etc.). The utterance situation u constrains the world in a certain way, depending on how the roles for discourse situations, connections, and described situation are to be filled. For instance, an utterance *I am crying* defines a meaning relation:

$$d, c[[I \text{ am crying}]]e$$

Given a discourse situation d , connections c , and a described situation e , this holds just in case there is a location L and a speaker s such that s is speaking at L , and, in e , s is crying at L .

In interpreting the utterance of an expression f in context, there is a flow of information, partly from the linguistic form encoded in f and partly from contextual factors provided by the utterance situation u . These are combined to form a set of constraints on the described situation e . This situation is not uniquely determined; there may be several situations that satisfy the constraints. The meaning of an utterance of f and hence its interpretation are influenced by other factors such as stress, modality, and intonation. However, the situation in which f is uttered and the situation e described by this utterance seem to play the most influential roles.

Guide to Literature

Ground-breaking work on STASS is due to the late Jon Barwise, well-known mathematical logician,

and John Perry, prominent philosopher of language and mind. Barwise and Perry were the founders of Stanford University's Center for the Study of Language and Information (CSLI), which became almost synonymous with STASS research. In the beginning, the development of situation theory was hampered by a lack of appropriate tools. Later, the theory assembled its foundations based on innovations coming from set theory (Barwise and Etchemendy, 1987; Aczel, 1988). Barwise and Seligman (1997) further advanced the theory by introducing the concept of an information channel, which preserves information as it is transmitted through a system. Their work is in the spirit of Dretske's (1981) landmark work on information flow.

It is impossible to do justice to the profundity of STASS in a brief summary of this kind. The reader is referred to two seminal books, Barwise and Perry (1983) and Devlin (1991), for a thorough understanding. Although somewhat dated, the former is densely packed with excellent semantic common sense. The latter volume proposes a streamlined vocabulary and pays close attention to the foundations; it is the only modern introduction to STASS. (However, it does not render the Barwise and Perry volume obsolete; each book has its own merits.) Seligman and Moss (1997) is a beneficial survey that is mathematically demanding; it also has an excellent bibliography.

Various versions of situation theory have been applied to a number of linguistic issues (mainly) in English. The ideas emerging from research in situation semantics have also been coalesced with well-developed linguistic theories and have led to rigorous formalisms (Fenstad *et al.*, 1987). On the other hand, situation semantics has been compared to another influential approach to the theory of meaning, discourse representation theory (DRT).

Indexicals, demonstratives, referential uses of definite descriptions, deictic uses of pronouns, tense markers, and names all have technical treatments in situation semantics. Gawron and Peters (1990) focused on the semantics of pronominal anaphora and quantification. They argued that the ambiguities of sentences with pronouns can be resolved with an approach that represents anaphoric relations syntactically. They use a relational framework that considers anaphoric relations as relations between utterances in context. Cooper (1991, 1996) offered painstaking studies of linguistic problems to which situation semantics has been applied with some success. Tin and Akman (1994, 1996) showed how situation theory can be given a computational twist. They implemented a prefatory prototype (named BABY-SIT for obvious reasons) to program some practical

problems, including anaphora resolution. Devlin and Rosenberg (1996) explored applications of situation theory to the study of language use in everyday communication to improve human–computer interaction.

There used to be a specialized series of conferences devoted to recent developments in STASS. The first three volumes of proceedings were published as Cooper *et al.* (1990), Barwise *et al.* (1991), and Aczel *et al.* (1993). Nowadays, it is possible to find situation–theoretic papers dispersed in numerous conferences on logic, language, and information.

Finally, Devlin (2004) provides – despite the specific sounding title – a general appraisal of what STASS is all about; it may be consulted to get a better grasp of the historical developments that shaped STASS. Many of the Barwise papers reviewed by Devlin can be found in Barwise (1989), a fertile collection for technically oriented readers.

Social Construction and Language

Nonanalytic Approaches

According to Georg Wilhelm Friedrich Hegel the topic of "language and social construction" encompasses everything there is. I note this all embracing approach to contrast it with how these topics are discussed today. This article will focus on one view concerning the relation between language and social construction, namely John Searle's approach, which at the same time will serve to introduce into the fundamental problems. It will be necessary, however, to show first how this specific way of situating and addressing the problem evolved.

Subsequent to Hegel one can distinguish roughly four lines of thought: (1) the social theorists, ranging from Karl Marx through Emile Durkheim to Max Weber and modern sociology, (2) hermeneutical philosophers, from Wilhelm Dilthey through Edmund Husserl and Maurice Merleau-Ponty to modern post-structuralism, (3) the analytic philosophers starting with Gottlob Frege, Bertrand Russell, and Ludwig Wittgenstein up to modern analytical philosophy. Specific problems of social constructions are (4) also discussed in various disciplines such as jurisprudence, economics, and political science, sometimes accompanied by philosophical inclinations. However, none of these traditions is totally exclusive of the others. Even though the topic 'language and social

construction' features in all such discussions, this article will only consider the analytical tradition.

Analytic Approaches

Early Analytic Approaches and Social Construction

The second generation of Analytic philosophers were in the beginning firmly rooted in either logical positivism or ordinary language philosophy. Their original objectives were to reveal the logical structure of language or to solve philosophical puzzles by analyzing the ordinary usage of words. Both schools of thought shared an empiricist and scientific attitude. For this early reason, analytical philosophers showed little interest in social and political reality or history. A few philosophers within the analytic tradition did pay attention to institutions, however, most notably Peter Winch (1958) and David Lewis (1969). Winch argued on the basis of Wittgenstein's *Philosophical Investigations* that explaining human action requires an understanding of the forms of life established in the society wherein the action is carried out; hence objective, culture independent explanations like those found in the natural sciences are unavailable in the social sciences. David Lewis, on the other hand, gave a game theoretic account of conventions as a solution to recurrent coordination problems. While Winch tried to justify the traditional distinction between the approaches in the natural sciences and the social sciences, Lewis examined ways of reconstructing classical arguments of social philosophy using modern

means. Recently John Searle has developed an ontology of social facts and, in particular, of social institutions based on his speech act theory and philosophy of mind (Searle, 1995). This development marks the beginning of a renewed interest in social facts within analytic philosophy.

John Searle's Approach

Social Construction John Searle's first major work was on speech acts, where he first pointed out the distinction between brute facts and institutional facts, and highlighted the particular role of constitutive rules in the creation of institutions (Searle, 1969: 50–53). He subsequently based the foundations of speech act theory on his philosophy of mind (Searle, 1983). Searle then returned to institutional facts to elaborate his point more systematically. He uses three concepts as building blocks for his theory: the assignment of functions, collective intentionality, and constitutive rules of the form “X counts as Y in context C” (Searle, 1995: 13). Taking the “scientific worldview” for granted, Searle starts with the puzzle of how it is possible that there are objective social facts, such as “George Washington was the first president of the U.S.,” within a world composed entirely of minute physical particles. Searle's basic proposal is that we assign functions both to naturally occurring objects (e.g., using a stone as a paperweight) and to those created for the purpose of performing an assigned function (e.g., using a hammer) (Searle, 1995: 13–23). Searle argues that such functions are never discovered in nature, like the natural properties of weight, color, etc., and cannot be completely reduced to causal explanations. Instead they are always imposed on things by intentional actors. Functions thus are always observer relative. This distinction is crucial because it allows us to mark the difference between features of reality that are observer independent (e.g., gravity, force) and usually described by the natural sciences and those that are observer dependent and usually dealt with by the social sciences. The latter features are always partly constituted by an ontologically subjective set of attributes (intentions); nevertheless they can in the case of institutions still be epistemically objective.

Searle also uses the imposition of functions to explain the meaning of words and signs. According to Searle, meaning arises whenever we assign functions to things as to symbolize, represent, or stand for something. Hence a red traffic light signals ‘Stop!’ because we have assigned this function to red lights in boxes at the roadside. Searle's theory of meaning is taken for granted. The relevant point here concerns only the relation between the natural world and the social world of animals and humans. While Searle

attempts to adhere to the program of realism he nevertheless makes frequent use of terms like intentions, functions, etc. According to Searle they are compatible with the scientific worldview of realism since he claims intentionality, the prerequisite for the imposition of functions, is a “higher level feature of the brain.”

Searle uses the same scheme of explanation to introduce the second building block of his theory, collective intentionality (Searle, 1995: 23–29). He sees collective intentionality or ‘we-intentionality’ as a “biologically primitive phenomenon” that cannot be reduced or eliminated in favor of something else. Searle, in particular, stipulates that it cannot be reduced to “individual intentions plus something else.” Whenever people engage in cooperative social action, Searle argues, there has to be “collective intentionality at a higher level.” This concept holds true for a violinist playing in an orchestra and even for certain hostile activities like litigants in a legal proceeding or two faculty members trading insults at a cocktail party. Searle holds that all these are social facts that involve the ‘we intentions’ of the parties.

Finally, constitutive rules of the form “X counts as Y in the context C” are employed to explain the difference between brute facts and institutional facts (Searle, 1995: 27–29). According to Searle, brute facts, such as that gold is a chemical element, exist independently of social institutions. Only the sentence “gold is an element” depends on the institutions of language and science. Institutional facts, on the other hand, such as the scoring rules of football, depend for their very existence on conventional agreements and on the acceptance of such conventions by the group taking part in the game; they are not pre-given. To explain institutional facts Searle further distinguishes between regulative and constitutive rules. Regulative rules govern preexisting activities, like driving on the right side of the road. The activity of driving (on either side of the road) existed before it was made obligatory to drive on the right. Constitutive rules, on the other hand, create the very possibility of an activity. Without the rules of football there would be no such game, and kicking a ball between two posts would not count as scoring. Searle concedes that the distinction between regulative rules and constitutive rules cannot always be strictly drawn as many constitutive rules rest on preexisting activities that might be governed by regulative rules. In any case, it is a distinction within the realm of social facts. All institutions are then built by using a system of constitutive rules of the form “X counts as Y in the context C” (Searle, 1995: 43–51). Thus, shooting a ball between posts (X) counts as scoring (Y) in a football game (C). The X term stands for some object

or activity, to which (via collective intentionality) a certain status function has been assigned.

The most obvious example of social facts, explainable along the lines of Searle's analysis, is an institution such as money. Status functions are assigned on certain pieces of paper. Such statements require an involvement of collective intentionality; hence the paper functions as money only as long as we consider it to be money. It is moreover dependent on a specific context. The formula is useful for explaining standard cases, though it allows as well for the reflection of unusual cases. A standard case might be: 'Bills issued by the Bureau of Engraving and Printing (X) count as money (Y) in the United States (C).' The existence of a 'cigarette currency' in post-war Germany might be an unusual case: 'American cigarettes (X) counted as money (Y) in post-war Germany (C).' With these basic distinctions at hand it is possible to give a 'hierarchical taxonomy of (certain types of) facts' starting from brute facts and going up to institutional facts (Searle, 1995: 37–43).

The Role of Language Searle's approach makes obvious why social construction is a linguistic activity. Collective intentionality alone does not require language or any symbolic means as it may be presupposed that even a pack of wolves hunting together are engaged in a collective enterprise. Indeed, Searle assumes that animals have intentionality. The difference comes only with the imposition of the status functions.

In moving from the X to the Y term the matter of the X term does not change, it only acquires a new meaning. It is used to symbolize something that exists only by virtue of a collective agreement. This theory requires some elucidation. Symbols are often (but not always) used to refer to objects that exist independently of the symbols and even independently of language. The symbol 'cat' refers to cats; and cats exist independently of any symbol referring to them. The imposition of status functions on something, on the other hand, creates a new category of objects or actions that have not existed prior to symbolization and collective agreement. The difference is made obvious by comparing social behavior of animals and humans. Certain animals might live in lifelong pair-bonding but they will nevertheless not be married, as they do not have the institution of marriage. That humans are married cannot be read off their behavior either but has to be declared in a certain situation. The declaration of marriage is an indispensable linguistic activity as only by virtue of the symbolic act are certain rights and duties granted. Institutions hence create reasons for action that depend on

forms of symbolization. The initial act is usually thereafter represented by some symbolic means, Searle calls them status indicators, as e.g., wedding rings or a marriage certificate.

A further sign evincing their linguistic nature is that status functions are intensional and cannot be replaced *salva veritate* by coextensive expressions. Hence, even if it is true that 'marriage ruins the sex life,' it does not follow that 'exchanging rings counts as "ruining sex life" in the context of a church ceremony.'

It should be kept in mind that the formula is meant not only to explain the creation of institutions out of brute facts but as a general explanation. Therefore, institutional facts are permissible at the place of the X term so that social facts can be reiterated. Indeed, Searle notes that language itself is an institutional fact that can be analyzed using the formula.

However, this feature reveals a fundamental problem. One of Searle's main objectives is to show how institutional facts emerge out of natural facts through language. If, however, language is an institutional fact in itself, the formula merely highlights a structure within the realm of institutional facts but cannot ultimately explain the emergence of institutional facts. Searle addresses the problem merely by stating that language is a special kind of institutional fact, namely one that is "designed to be a self-identifying category of institutional fact" (Searle, 1995: 73).

Critical Assessment

Searle labels his approach "philosophy of society," analogous to classic fields like philosophy of language or philosophy of mind. Three kinds of criticisms in reaction to Searle's proposal have emerged. Those who agree in principle with Searle's line of thought dispute specifically the concepts of collective action and collective intentionality (Gilbert, 1989; Bratman, 1999; Tuomela, 2002). There are, on the other hand, two kinds of criticisms questioning Searle's approach in principle. Some philosophers hold that Searle misses the fundamental role ordinary language plays in conceiving reality at all, since Searle presupposes implicitly that the world as described by the natural sciences can be attained independently and prior to the everyday social world, hence independently of ordinary language. Social scientists, on the other hand, criticize Searle for failing to account for social facts properly, since social facts pertain to the explanation of actions, a feature Searle omits in his philosophy of society. The different kinds of criticism do not exactly correspond with the lines of thought mentioned in the beginning; however they show that the philosophical discussion is still divided over fundamental questions.

Speech Acts

Y Huang, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

Speech act theory, though foreshadowed by the Austrian philosopher Ludwig Wittgenstein's views about language-games, is usually attributed to the Oxford philosopher J. L. Austin. The basic ideas, which were formed by him in the late 1930s, were presented in his lectures given at Oxford in 1952–1954, and later in his William James Lectures delivered at Harvard in 1955. These lectures were finally published posthumously as *How to do things with words* in 1962. After his death in 1960, Austin's ideas were refined, systematized, and advanced, especially by his Oxford pupil, the American philosopher John R. Searle. Simply stated, the central tenet of speech act theory is that the uttering of a sentence is, or is part of, an action within the framework of social institutions and conventions. Put in slogan form, saying is (part of) doing, or words are (part of) deeds.

J. L. Austin

The Performative/Constative Dichotomy

In the 1930s, a very influential school of thought in philosophy was logical positivism, developed by a group of philosophers and mathematicians principally in Vienna. One of the central doctrines of logical positivism is what is now called 'the descriptive fallacy,' namely, the view that the only philosophically interesting function of language is that of making true or false statements. A particular version of the descriptive fallacy is the verificationist thesis of

meaning, namely, the idea that 'unless a sentence can, at least in principle, be verified (i.e., tested for its truth or falsity), it was strictly speaking meaningless' (Levinson, 1983: 227). On such a view, sentences that are not used to make verifiable or falsifiable propositions are simply meaningless.

It was against this philosophical background that Austin set about to develop his theory of speech acts (Austin, 1962). He made two important observations. First, he noted that some ordinary language sentences such as those in (1) are not employed to make a statement, and as such they cannot be said to be true or false.

- (1a) Good afternoon!
- (1b) Is he a Republican?
- (1c) Come in, please.

Secondly and more importantly, Austin observed that there are ordinary language declarative sentences that similarly resist a truth-conditional analysis. The point of uttering such sentences is not just to say things, but also actively to do things. In other words, such utterances have both a descriptive and an effective aspect. Accordingly, Austin called them 'performatives,' and he distinguished them from assertions, or statement-making utterances, which he called 'constatives.' In other words, performatives are utterances that are used to do things or perform acts, as in (2), whereas constatives are utterances that are employed to make assertions or statements, as in (3).

- (2a) I christen/name this ship the Princess Elizabeth.
- (2b) I now pronounce you man/husband and wife.
- (2c) I promise to come to your talk tomorrow afternoon.
- (3a) My daughter is called Elizabeth.

- (3b) A freshly baked loaf doesn't cut easily.
- (3c) Maurice Garin won the first Tour de France in 1903.

Unlike those in (3), the declarative sentences in (2) have two characteristics: (i) they are not used intentionally to say anything, true or false, about states of affairs in the outside world, and (ii) their use constitutes (part of) an action, viz., that of christening/naming a ship in (2a), that of pronouncing a couple married in (2b), and that of promising in (2c). In addition, there are two further differences between (2a–b) and (2c). The first is that while (2a–b) is part of a conventional or ritual behavior supported by institutional facts (see also Strawson, 1964), (2c) is not. Secondly, while the performative verb, that is, the verb naming the action while performing it in (2a–b) is in general an essential element and cannot be omitted, it can in (2c). In other words, whereas, for example, we cannot christen/name a ship without using the verb *christen* or *name*, we can make a promise without using the verb *promise*, as in (4).

- (4) I'll come to your talk tomorrow afternoon.

Performatives can further be divided into two types: explicit and implicit. Explicit performatives are performative utterances that contain a performative verb that makes explicit what kind of act is being performed. By contrast, implicit performatives are performative utterances in which there is no such verb. Thus, the performatives in (2) are explicit ones, and the performative in (4) is an implicit one.

Austin also isolated a number of syntactic and semantic properties of explicit performatives in English: (i) explicit performatives contain a performative verb, (ii) the performative nature of such a verb can be reinforced by adding the adverb *hereby*, and (iii) explicit performatives occur in sentences with a first-person singular subject of a predicate (verb) in the simple present tense, indicative mood, and active voice.

However, as Austin himself was aware, there are exceptions. Explicit performatives can sometimes take a first-person plural subject, as in (5); a second-person singular or plural subject, as in (6); and a third-person singular or plural subject, as in (7). In addition, there are cases where the explicit performative verb is 'impersonal,' that is, it does not refer to the speaker, as in (8). Furthermore, as (6), (7), and (8) show, explicit performatives can occur in sentences where the verb is in the passive voice. Finally, as (9) indicates, they can also occur in sentences of present progressive aspect.

- (5) We suggest that you give up smoking immediately.

- (6) You are fired.
- (7) Passengers are hereby requested to wear a seat belt.
- (8) Notice is hereby given that shoplifters will be prosecuted.
- (9) I am warning you not to dance on the table.

Austin's Felicity Conditions on Performatives

As already mentioned, it makes no sense to call a performative true or false. Nevertheless, Austin noticed that for a performative to be successful or 'felicitous,' it must meet a set of conditions. For example, one such condition for the speech act of naming is that the speaker be recognized by his or her community as having the authority to perform that act; for the speech act of ordering, the condition is that the speaker have authority over the addressee; and finally, for the speech act of promising, one condition is that what is promised by the speaker must be something the addressee wants to happen. Austin called these conditions 'felicity conditions,' of which he distinguished three types, as shown in (10).

- (10) Austin's felicity conditions on performatives
 - (10a) (i) There must be a conventional procedure having a conventional effect.
 - (10a) (ii) The circumstances and persons must be appropriate, as specified in the procedure.
 - (10b) The procedure must be executed (i) correctly and (ii) completely.
 - (10c) Often
 - (i) the persons must have the requisite thoughts, feelings and intentions, as specified in the procedure, and
 - (ii) if consequent conduct is specified, then the relevant parties must so do.

Violation of any of the conditions in (10) will render a performative 'unhappy' or infelicitous. If conditions *a* or *b* are not observed, then what Austin described as a 'misfire' takes place. For instance, in England, a registrar conducting a marriage ceremony in an unauthorized place will violate condition *a* (i), thus committing a misfire. The same is true for a clergyman baptizing the wrong baby, because in this case, condition *a* (ii) is not fulfilled. Next, as an illustration of a violation of condition *b* (i), consider the case of a bridegroom not saying the exact words that are conventionally laid down for a Church of England marriage ceremony. As to condition *b* (ii), it dictates that the procedure be complete. Thus, in making a bet, the bet is not 'on' unless *You are on* (or something with the same effect) is uttered by the addressee; in Austin's terminology, this counts as a satisfactory 'uptake,' the absence of which will again

cause a misfire. Finally, if condition *c* is violated, then what Austin called an ‘abuse’ is committed (including, but not only, cases of insincerity). Examples include: congratulating someone when one knows that he or she passed his or her examination by cheating (condition *c* (i)); making a promise when one already intends to break it (condition *c* (ii)); and marrying without intending to consummate the marriage (see also Sadock’s (2004) discussion of these conditions in terms of misinvocation, misexecution, and abuse).

Locutionary, Illocutionary, and Perlocutionary Speech Acts

The initial distinction made by Austin between performatives and constatives was soon to be rejected by him in favor of a general theory of speech acts. In fact, as pointed by Levinson (1983: 231), there are two internal shifts in Austin’s arguments. First, there is a shift from the view that performatives are a special class of sentences/utterances with peculiar syntactic and semantic properties to the view that there is a general class of performatives that encompasses both explicit and implicit performatives, the latter including many other types of sentences/utterances. The second shift is from the performative/constative dichotomy to a general theory of speech acts, of which the various performatives and constatives are just special sub-cases.

What led Austin to abandon the performative/constative dichotomy? In the first place, he noted that like performatives, constatives are also subject to the felicity conditions stated in (10). Consider the so-called ‘Moore’s paradox,’ illustrated by (11).

- (11) ?Princess Diana died in a fatal car crash in Paris with Dodi Al Fayed, but I don’t believe it.

This utterance is infelicitous because it violates condition *c* (i) in (10) above. In the same vein, if someone utters (12) when he or she knows that John does not in fact have a wife, then its presupposition will not go through (see **Presupposition**). The reason the presupposition fails to carry through is that condition *a* (ii) in (10) above is not adhered to.

- (12) I’m sure John’s wife is a feminist.

Secondly, Austin observed that performatives and constatives may be impossible to distinguish even in truth-conditional terms. On the one hand, there are ‘loose’ constatives that may not be assessed strictly by means of truth conditions, as in (13). On the other hand, there are utterances like those in (14) that pass the *hereby* test and therefore are performatives by definition but that nevertheless are used to state or assert. In these cases, the performatives must be

counted simultaneously as constatives. On the basis of such evidence, Austin concluded that constatives are nothing but a special class of performatives, and that the two-way distinction between performatives, as action-performers, and constatives, as truth-bearers, can no longer be maintained.

- (13a) France is hexagonal.
 (13b) The fridge is empty.
 (13c) New York is sixty miles from where I live.
 (14a) I hereby state that Da Vinci started to paint *Mona Lisa* in 1503.
 (14b) I hereby tell you that the bill is right.
 (14c) I hereby hypothesize that there is water on Mars.

Consequently, Austin claimed that all utterances, in addition to meaning whatever they mean, perform specific acts via the specific communicative force of an utterance. Furthermore, he introduced a three-fold distinction among the acts one simultaneously performs when saying something, as illustrated in (15):

- (15) (A speech act’s three facets)
 (i) Locutionary act: the production of a meaningful linguistic expression.
 (ii) Illocutionary act: the action intended to be performed by a speaker in uttering a linguistic expression, by virtue of the conventional force associated with it, either explicitly or implicitly.
 (iii) Perlocutionary act: the bringing about of consequences or effects on the audience through the uttering of a linguistic expression, such consequences or effects being special to the circumstances of utterance.

A locutionary act is the basic act of speaking, which itself consists of three related sub-acts: (i) a phonic act of producing an utterance-inscription; (ii) a phatic act of composing a particular linguistic expression in a particular language; and (iii) a rhetic act of contextualizing the utterance-inscription (Austin, 1962). The first of these three sub-acts is concerned with the physical act of producing a certain sequence of vocal sounds (in the case of spoken language), or a set of written symbols (in the case of written language). The second refers to the act of constructing a well-formed string of sounds/symbols (a word, phrase, or sentence in a particular language). The third sub-act is responsible for tasks such as assigning reference, resolving deixis, and disambiguating the utterance-inscription lexically and/or grammatically (see **Deixis and Anaphora: Pragmatic Approaches**).

The illocutionary act refers to the fact that when we say something, we usually say it with some purpose in mind. In other words, an illocutionary act refers to the type of function the speaker intends to fulfill, or

the action the speaker intends to accomplish in the course of producing an utterance; it is also an act defined within a system of social conventions. In short, it is an act accomplished in speaking. Examples of illocutionary acts include accusing, apologizing, blaming, congratulating, declaring war, giving permission, joking, marrying, nagging, naming, promising, ordering, refusing, swearing, and thanking. The functions or actions just mentioned are also commonly referred to as the illocutionary 'force' (or 'point') of the utterance. Illocutionary force is frequently conveyed by what Searle (1969) called an 'illocutionary force indicating device' (IFID), the most direct and conventional type of which is an explicit performative in the form of (16) (where Vp stands for performative verb). Indeed, the term 'speech act' in its narrow sense is often taken to refer exclusively to illocutionary acts.

(16) I (hereby) Vp you (that) S

It should be mentioned at this point that the same linguistic expression can be used to carry out a wide variety of different speech acts, so that the same locutionary act can count as having different illocutionary forces in different contexts. Depending on the circumstances, one may utter (17) to make a threat, to issue a warning, or to give an explanation.

(17) The gun is loaded.

In fact, Alston (1994) has argued that the meaning of a sentence consists in its having a certain illocutionary act potential (IAP) that is closely and conventionally associated with its form. On this view, to know what a sentence means is to know what range of illocutionary acts it can be conventionally used to perform.

Conversely, the same speech act can be performed by different linguistic expressions, or the same illocutionary force can be realized by means of different locutionary acts. The utterances in (18), for example, illustrate different ways of carrying out the same speech act of requesting.

(18) (At ticket office in railway station)

(18a) A day return ticket to
Oxford, please.

(18b) Can I have a day return ticket to
Oxford, please?

(18c) I'd like a day return ticket to Oxford.

Finally, a perlocutionary act concerns the effect an utterance may have on the addressee. Put slightly more technically, a perlocution is the act by which the illocution produces a certain effect in or exerts a certain influence on the addressee. Still another way to put it is that a perlocutionary act represents a consequence or by-product of speaking, whether intentional or not.

The effect of the act being performed by speaking is generally known as the perlocutionary effect. There is an extensive literature on the differentiation between locutionary, illocutionary, and perlocutionary acts (see e.g., Sadock (2004) for a survey).

J. R. Searle

Searle's Felicity Conditions on Speech Acts

Just as its truth conditions must be met by the world for a sentence to be said to be true, its felicity conditions must also be fulfilled by the world for a speech act to be said to be felicitous. Searle (1969) took the view that the felicity conditions put forward by Austin are not only ways in which a speech act can be appropriate or inappropriate, but that they also jointly constitute the illocutionary force. Put in a different way, the felicity conditions are the constitutive rules – rules that create the activity itself – of speech acts. On Searle's view, to perform a speech act is to obey certain conventional rules that are constitutive of that type of act. Searle developed the original Austinian felicity conditions into a neo-Austinian classification of four basic categories, namely (i) propositional content, (ii) preparatory condition, (iii) sincerity condition, and (iv) essential condition. As an illustration of these conditions, consider (19).

- (19) Searle's felicity conditions for promising
- (i) propositional content: future act A of S
 - (ii) preparatory: (a) H would prefer S's doing A to his not doing A, and S so believes
 - (b) It is not obvious to both S and H that S will do A in the normal course of events
 - (iii) sincerity: S intends to do A
 - (iv) essential: the utterance of e counts as an undertaking to do A

where S stands for the speaker, H for the hearer, A for the action, and e for the linguistic expression.

The propositional content condition is in essence concerned with what the speech act is about. That is, it has to do with specifying the restrictions on the content of what remains as the 'core' of the utterance (i.e., Searle's propositional act) after the illocutionary act part is removed. For a promise, the propositional content is to predicate some future act of the speaker, whereas the preparatory conditions state the real-world prerequisites for the speech act. In the case of a promise, the latter are roughly that the addressee would prefer the promised action to be accomplished, that the speaker knows this, but also that it is clear to both the speaker and the addressee that what is promised will not happen in the normal course of action. Next, the sincerity condition must be satisfied if the act is to be performed sincerely. When carrying out

an act of promising, the speaker must genuinely intend to keep the promise. Notice that if the sincerity condition is not fulfilled, the act is still performed, but there is an abuse, to use Austin's term. Finally, the essential condition defines the act being performed in the sense that the speaker has the intention that his or her utterance will count as an act, and that this intention is recognized by the addressee. Thus for a promise, the speaker must have the intention to create an obligation to act. Failure to meet the essential condition has the consequence that the act has not been carried out.

Searle's Typology of Speech Acts

Can speech acts be classified, and if so, how? Austin (1962) grouped them into five types: (i) verdictives: giving a verdict, (ii) exercitives: exercising power, rights or influence, (iii) commissives: promising or otherwise undertaking, (iv) behabitives: showing attitudes and social behavior, and (v) expositives: fitting an utterance into the course of an argument or conversation. Since then, there have been many attempts to systematize, strengthen, and develop the original Austinian taxonomy (Bach and Harnish, 1979; Allan, 2001; Bach, 2004). Some of these new classifications are formulated in formal/grammatical terms, others, in semantic/pragmatic terms, and still others, on the basis of the combined formal/grammatical and semantic/pragmatic modes (see Sadock (2004) for a review). Of all these (older and newer) schemes, Searle's (1975a) neo-Austinian typology remains the most influential. Under Searle's taxonomy, speech acts are universally grouped into five types along four dimensions: (i) illocutionary point, (ii) direction of fit between words and world, (iii) expressed psychological state, and (iv) propositional content (see also Searle (2002)). The five types of speech acts are further explained next.

(i) Representatives (or assertives; the constatives of the original Austinian performative/constative dichotomy) are those kinds of speech acts that commit the speaker to the truth of the expressed proposition and thus carry a truth-value. They express the speaker's belief. Paradigmatic cases include asserting, claiming, concluding, reporting, and stating. In performing this type of speech act, the speaker represents the world as he or she believes it is, thus making the words fit the world of belief.

(20) The Berlin Wall came down in 1989.

(ii) Directives are those kinds of speech acts that represent attempts by the speaker to get the addressee to do something. They express the speaker's desire/wish for the addressee to do something. Paradigmatic

cases include advice, commands, orders, questions, and requests. In using a directive, the speaker intends to elicit some future course of action on the part of the addressee, thus making the world match the words via the addressee.

(21) Put the cake in the oven.

(iii) Commissives are those kinds of speech acts that commit the speaker to some future course of action. They express the speaker's intention to do something. Paradigmatic cases include offers, pledges, promises, refusals, and threats. In the case of a commissive, the world is adapted to the words via the speaker himself.

(22) I'll never buy you another computer game.

(iv) Expressives are those kinds of speech acts that express a psychological attitude or state of the speaker such as joy, sorrow, and likes/dislikes. Paradigmatic cases include apologizing, blaming, congratulating, praising, and thanking. There is no direction of fit for this type of speech act.

(23) Well done, Elizabeth!

(v) Declarations (or declaratives) are those kinds of speech acts that effect immediate changes in some current state of affairs. Because they tend to rely on elaborate extralinguistic institutions for their successful performance, they may be called institutionalized performatives. In performing this type of speech act, the speaker brings about changes in the world; that is, he or she effects a correspondence between the propositional content and the world. Paradigmatic cases include (officially) opening a bridge, declaring war, excommunicating, firing from employment, and nominating a candidate. As to the direction of fit, it is both words-to-world and world-to-words.

(24) I object, Your Honor.

Illocutional point (or speech act type), direction of fit, and expressed psychological state can be summarized as in (25).

(25) Illocutionary point/Speech act type	Direction of fit	Expressed psychological state
representative	words-to-world	belief
directive	world-to-words	desire
commissive	world-to-words	intension
expressive	none	variable
declaration	both	none

Indirect Speech Acts

What is an indirect speech act? Most of the world's languages have three basic sentence types: declarative, interrogative, and imperative. In some languages,

the three major sentence types are distinguished morphologically and/or syntactically; as instances, compare Somali, Greenlandic, or Lakhota (Lakota) (see Huang (2006) for further discussion). The three sentence types are typically associated with the three basic illocutionary forces, namely, asserting/stating, asking/questioning, and ordering/requesting, respectively.

In the case of a direct match between a sentence type and an illocutionary force, we have a direct speech act. In addition, explicit performatives, which happen to be in the declarative form, are also taken to be direct speech acts, because they have their illocutionary force explicitly named by the performative verb in the main part (or 'matrix clause') of the sentence. On the other hand, if there is no direct relationship between a sentence type and an illocutionary force, we are faced with an indirect speech act. Thus, when an explicit performative is used to make a request, as in (26), it functions as a direct speech act; the same is the case when an imperative is employed, as in (27). By comparison, when an interrogative is used to make a request, as in (28), we have an indirect speech act.

(26) I request you to pass the salt.

(27) Pass the salt.

(28) Can you pass the salt?

In short, the validity of the distinction between direct and indirect speech acts is dependent upon whether or not one subscribes to what Levinson (1983: 264, 274) has called the 'literal force hypothesis' – the view that there is a direct structure-function correlation in speech acts and that sentence forms are direct reflexes of their underlying illocutionary forces.

There are, however, problems at the very heart of the literal force hypothesis. One is that there are cases of speech acts where even the direct link between performative verbs and speech acts breaks down. Consider (29).

(29) I promise to sack you if you don't finish the job by this weekend.

In (29), the performative verb is *promise*, but the force that is most naturally ascribed to this speech act is that of either a threat or a warning. This shows that, contrary to the literal force hypothesis, we cannot always identify speech acts, even with sentences containing a performative verb.

Secondly and more importantly, as also pointed out by Levinson (1983: 264), most usages are indirect. The speech act of requesting, for example, is very rarely performed by means of an imperative in English. Instead, it is standardly carried out indirectly.

Furthermore, there are probably infinitely many varieties of sentences that can be used to indirectly make a request, as shown in (30).

(30a) I want you to put the cake in the oven.

(30b) Can you put the cake in the oven?

(30c) Will you put the cake in the oven?

(30d) Would you put the cake in the oven?

(30e) Would you mind putting the cake in the oven?

(30f) You ought to put the cake in the oven.

(30g) May I ask you to put the cake in the oven?

(30h) I wonder if you'd mind putting the cake in the oven?

As to how to analyze indirect speech acts, there are roughly three approaches. The first is to assume the existence of a dual illocutionary force (as proposed by Searle, 1975b). On this assumption, indirect speech acts have two illocutionary forces, one literal or direct, and the other nonliteral or indirect. While the literal force is secondary, the nonliteral force is primary. Next, whether an utterance operates as an indirect speech act or not has to do with the relevant felicity conditions. For example, (28) both infringes the felicity condition for a question and queries the preparatory condition for a request. This explains why it can function as an indirect speech act, whereas (31), for instance, cannot; the reason is that in the case of (31), felicity conditions are irrelevant.

(31) Salt is made of sodium chloride.

Finally, on Searle's view, because a speaker's performing and an addressee's understanding an indirect speech act always involves some kind of inference, the question is how this inference can be computed. Searle's suggestion is that it can be computed along the general lines of the rational, cooperative model of communication articulated by Grice (1989) (see **Cooperative Principle**).

One interesting characteristic of indirect speech acts is that they are frequently conventionalized (see, e.g., Morgan, 1978). This can be illustrated by the fact that of various, apparently synonymous linguistic expressions, only one may conventionally be used to convey an indirect speech act, as illustrated in (32).

(32a) Are you able to pass the salt?

(32b) Do you have the ability to pass the salt?

Under Searle's analysis, both (32a) and (32b) would be expected to be able to perform the indirect speech act of requesting, because (i) they are largely synonymous with (28), and (ii) they, too, inquire about the satisfaction of the addressee-based preparatory condition for making a request. But this expectation is not fulfilled.

Searle's response to this puzzle is that there is also a certain degree of conventionality about indirect speech acts, and that this may be accounted for in terms of conventions of meaning/usage. Inspired by this insight, Morgan (1978) developed the notion of 'short-circuited implicature' to cover inference involved in cases like (28) (see **Implicature**). While the relevant implicature is in principle calculable, in practice it is not calculated in cases like these. From a linguistic point of view, the conventionality here is correlated with the possible occurrence of *please*. While *please* can be inserted before the verb *pass* in (26)–(28), it cannot in (32), as shown in (33).

- (33a) I request you to please pass the salt.
- (33b) Please pass the salt.
- (33c) Can you please pass the salt?
- (33d) ?Are you able to please pass the salt?
- (33e) ?Do you have the ability to please pass the salt?

Furthermore, the conventionality indicated by *please* in (33a) and (33b) is one of meaning, hence the speech act of requesting is performed directly. By contrast, the conventionality signaled by *please* in (33c) is one of usage, and thus we have an indirect speech act.

A second, rather similar, approach is due to Gordon and Lakoff (1975). In their analysis, there are inference rules called 'conversational postulates' that reduce the amount of inference needed to interpret an indirect speech act. Thus, in the case of (28), if the interpretation as a question cannot be intended by the speaker, then the utterance will be read as being equivalent to his or her having said (26), thus resulting in the performance of the indirect speech act of requesting. Stated this way, the conversational postulates proposed by Gordon and Lakoff can be seen as another reflection of the conventionality of indirect speech acts. As to the similarities and differences between Searle's and Gordon and Lakoff's analyses, the major similarity is that both accounts assume that the interpretation of indirect speech acts involves inference as well as conventionality; the major difference concerns the question of balance, namely, how much of the work involved in computing an indirect speech act is inferential and how much is conventional.

Finally, in contrast to the inferential models we have just discussed, there is the idiom model. In this model, sentences like (28) are semantically ambiguous, and the request interpretation constitutes a speech act idiom that involves no inference at all. On this view, (28) is simply recognized as a request, with no question being perceived. This is the position taken by Sadock (1974). There are, however, problems with this analysis, too. One is that it fails to

capture the fact that (in contrast to what is the case for idioms) the meaning of an indirect speech act can frequently (at least in part) be derived from the meaning of its components (the technical term for this is 'compositionality'); in addition, these would-be 'idioms' turn out to be quite comparable cross-linguistically (something which idioms are not). For example, an utterance like (34) may be used, with the same force as in English, in its Arabic, Chinese, German, or Modern Greek versions to indirectly request the addressee to switch on the central heating system (of course, always depending on the context).

- (34) 'It's cold in here.'

A further problem is that in the idiom model, an interpretation that takes into account the literal meaning or the direct illocutionary force of an indirect speech act is not allowed. This, however, leaves examples like (35) unexplained.

- (35) A: Can you pass the salt?
B: Yes, I can. (Here it is.)

Why, then, do people use indirect speech acts? One answer is that the use of indirect speech acts is in general associated with politeness. Indirect speech acts are usually considered to be more polite than their direct counterparts (see the considerable literature on the analysis of speech acts, especially the work on face-threatening acts (FTAs) like requests, complaints, and apologies in the tradition of Brown and Levinson's (1987) classical 'face-saving' politeness model).

Speech Acts and Culture

Cross-Cultural Variation

Many speech acts are culture-specific. This is particularly so in the case of institutionalized speech acts, which typically use standardized and stereotyped formulae and are performed in public ceremonies. A good example is provided by the speech act of divorcing. In some Muslim cultures, under the appropriate circumstances, the uttering of a sentence with the import of (36) three times consecutively by a husband to his wife will *ipso facto* constitute a divorce. By contrast, in Western cultures, no one (no matter what his or her religion is) can felicitously use (36) to obtain a divorce.

- (36) 'I hereby divorce you.'

But how about non-institutionalized speech acts? First of all, as said above, any given speech act may be culture-specific. Rosaldo (1982), for example, observed that the speech act of promising has no place among the Ilongots – a tribal group of hunters

and horticulturalists in the Philippines. She attributes the absence of this speech act in the conceptual repertoire of the Ilongot to a lack of interest in sincerity and truth in that community. The Ilongot, argues Rosaldo, are more concerned with social relationships than with personal intentions. On the basis of anthropological evidence such as this, Rosaldo claims that the universality of Searle's typology of speech acts cannot be maintained. Another example of this kind has been reported for the Australian aboriginal language Yolngu. According to Harris (1984: 134–135), there does not seem to be any speech act of thanking in the Yolngu speaker's repertoire.

Conversely, a given speech act may be present only in certain cultures. For example, in the Australian aboriginal language Walmajari, one finds a speech act of requesting that is based on kinship rights and obligations. The verb in question is *japirlyung* (Hudson, 1985), and the speech act may be called 'kinship-based requesting,' because it conveys a message meaning roughly 'I ask/request you to do X for me, and I expect you to do it simply because of how you are related to me'. Thus, for the speakers of Walmajari, it is very difficult to refuse a kinship-based speech act of requesting (see also Wierzbicka, 1991: 159–160). 'Exotic' speech acts such as the kinship-based requesting do not seem to be present in other East Asian or Western cultures.

Secondly, given a particular situation, pertinent speech acts are carried out differently in different cultures. For instance, in some East Asian and Western cultures, if one steps on another person's toes, one normally performs the speech act of apologizing. But apparently this is not the case among the Akans, a West African culture. As reported by Mey (2001: 287, crediting Felix Ameka), in that culture, such a situation does not call for apologies but calls for the expression of sympathy: "The focus is on the person to whom the bad thing has happened rather than the person who has caused the bad thing" (Mey, 2001: 287). Another example: while in English, thanks and compliments are usually offered to the hosts when leaving a dinner party, in Japanese society, apologies such as *o-jama itashimashita* 'I have intruded on you' are more likely to be offered by the guests. A similar speech act of apologizing is performed in Japanese upon receiving a present, when a Japanese speaker is likely to say something like *sumimasen* – the most common Japanese 'apology' formula or one of its variants. Conversely (as pointed out by many authors), apologies can be used in a much broader range of speech situations in Japanese than in English.

Thirdly, in different cultures/languages, the same speech act may meet with different typical responses.

For example, a compliment normally generates acceptance/thanking in English, but self-denigration in Chinese, Japanese, or even Polish. A typical compliment/response formula in Chinese would be something like (37).

- (37) A: *ni cai zuode zhen hao!*
 B: *nali, nali, wo bu hui zuocai.*
 A: *bie keqi. ni cai zhende zuode hen hao!*
 B: *ni tai keqi le.*
 A: 'You cook really well!'
 B: 'No, no, I don't really know how to cook properly.'
 A: 'Please don't be too modest. You really cook very well.'
 B: 'You're too kind.'

The same is even more true in Japanese. According to Mizutani and Mizutani (1987: 43), "[T]he Japanese will never accept a compliment without saying *ie* ['no']". Given the general Japanese reluctance to say 'no' under almost any other circumstances, the compliment response pattern is rather striking.

Fourthly, the same speech act may differ in its directness/indirectness in different cultures. Since the late 1970s, a great deal of research has been conducted on how particular kinds of speech acts, especially such face-threatening acts as requests, apologies, and complaints are realized across different languages. Of these investigations, the most influential is the large-scale Cross-Cultural Speech Act Realization Patterns Project (CCSARP) (Blum-Kulka *et al.*, 1989). In this project, the realization patterns of requesting and apologizing in German; Hebrew; Danish; Canadian French; Argentinean Spanish; and British, American, and Australian English were compared and contrasted. In the case of requests, the findings were that among the languages examined, the Argentinean Spanish speakers are the most direct, followed by the speakers of Hebrew. The least direct are the Australian English speakers, while the speakers of Canadian French and German are positioned at the midpoint of the directness/indirectness continuum. Building on the CCSARP, strategies for the performance of certain types of face-threatening acts in a much wider range of languages have since been examined. These languages include Catalan, Chinese, Danish, Dutch, French, German, Greek, Hebrew, Japanese, Javanese, Polish, Russian, Thai, Turkish, four varieties of English (British, American, Australian, and New Zealand), two varieties of French (Canadian and French), and eight varieties of Spanish (Argentinean, Ecuadorian, Mexican, Peninsular, Peruvian, Puerto Rican, Uruguayan, and Venezuelan). As a result of these studies, it has now been established that there is indeed

extensive cross-cultural variation in directness/indirectness in speech acting, especially in the realization of face-threatening acts (FTAs), and that these differences are generally associated with the different means that different languages utilize to realize speech acts. These findings have undoubtedly contributed to our better understanding of cross-cultural/linguistic similarities and differences in face-redressive strategies for FTAs (see Huang (2006) for detailed discussion).

Interlanguage Variation

A number of studies have recently appeared that explore speech acts in interlanguage pragmatics. Simply put, an interlanguage is a stage on a continuum within a rule-governed language system that is developed by L2 learners on the way to acquiring the target language. This language system is intermediate between the learner's native language and his or her target language.

Some of these studies investigate how a particular type of speech act is performed by non-native speakers in a given interlanguage; others compare and contrast the similarities and differences in the realization patterns of given speech acts between native and non-native speakers of a particular language. The best studied interlanguage is that developed by speakers of English as a second language. Other interlanguages that have been investigated include Chinese, German, Hebrew, Japanese, and Spanish (see Huang (2006) for further discussion).

A few recent formal and computational approaches to speech acts and speech act theory are worthy of note. One important theoretical development is the integration of speech acts with intensional logic, resulting in what is called 'illocutionary logic' (Searle and Vanderveken, 1985; Vanderveken, 1994, 2002). Similarly, Merin (1994) has endeavored to produce an algebra of what he calls 'social acts.' Finally, recent formalizations of various aspects of speech act theory in artificial intelligence and computational linguistics can be found in Perrault (1990), Bunt and Black (2000), and Jurafsky (2004) (see also Sadock, 2004).

Syncategoremata

G Klima, Fordham University, Bronx, NY, USA

The History of the Distinction

The medieval distinction between syncategorematic terms ('syncategoremata,' such as 'and,' 'or,' and 'not,' which merely combine other terms) and categorematic terms ('categoremata,' such as 'man,' 'Socrates,' and 'animal,' which can be predicated of things) dates back to the 6th-century grammarian Priscian, who in his *Institutiones Grammaticae*, who in his turn, attributes the idea to certain 'dialecticians.' Syncategoremata were commonly recognized by Stoics and Neo-Platonics (Pinborg, 1972: 60). However, Peripatetic dialecticians could also take their cue from Aristotle's relevant remark on the copula (the verb 'is' or its equivalent, joining subject and predicate), when he says that it is in itself "nothing, but co-signifies some combination, which cannot be thought of without the components" (*On Interpretation*, 16b24–25). In any case, according to Priscian, the dialecticians he refers to characterized syncategoremata in a similar way: such terms merely cosignify, in contrast to verbs and nouns, which, when combined, make a complete expression. With the emergence of the distinctive logical and grammatical literature of the Middle Ages in the 12th century continuing through the late 15th and early 16th centuries, discussions of syncategoremata became part of the characteristic genres of this literature (Sweeney, 2002), in which our medieval colleagues developed ever more sophisticated characterizations of syncategorematic terms, their distinction from categorematic terms, their function, and their nature. According to Norman Kretzmann's (1982) periodization, we can

distinguish the following main stages in the medieval career of syncategoremata:

1. Their emergence as the focal points of certain logical or semantic relationships or special problems of interpretation (in the 12th century, especially the latter half)
2. Their identification as a distinguishable set of topics worthy of development in separate treatises typically called syncategoremata (from the last quarter of the 12th century to the last quarter of the 13th century)
3. Their assimilation into general treatises on logic, sometimes as a group but sometimes dispersed in ways designed to associate particular syncategoremata with more general topics in logic to which they are appropriate
4. Their absorption into the sophisma literature (discussions of logical puzzles generated by problem sentences, the so-called 'sophismata'), in which a particular syncategorema may serve as the germ of a paradox the interest of which is often associated with metaphysics or natural philosophy more than with logic or semantics proper (from the first quarter of the 14th century to the disintegration of scholastic logic).

With the decline of scholastic logic, the logical treatises specifically devoted to syncategoremata or to sophismata focusing on the problems generated by syncategoremata became gradually extinct along with the rest of the characteristic logical literature of the Middle Ages. Yet, the distinction between categorematic and syncategorematic terms has never become entirely forgotten, and it keeps recurring in various guises also in modern philosophy. However, the most sophisticated accounts of the distinction are

still to be found in the medieval literature, which is the focus of the rest of this article.

Syntactic and Semantic Criteria of Drawing the Distinction

It is interesting that Priscian's remark involved two different and by no means equivalent criteria for distinguishing syncategorematic and categorematic terms. On what may be called the 'syntactic' criterion, categorematic terms are those that can function as subjects or predicates of propositions so that their combination yields a complete proposition, whereas syncategorematic terms cannot be subjects or predicates. On the 'semantic' criterion, however, syncategorematic terms are those that merely cosignify (i.e., signify in combination with some other term) but that in themselves do not signify anything. Apparently, the syntactic criterion provides a good test for sorting various parts of speech into either of the two members of the division. However, even if the criterion works, it does not seem to provide a principled reason why certain parts of speech behave in one way or the other. The semantic criterion seems to provide such a reason, but as it stands, it is rather vague.

Indeed, on closer inspection even the syntactic criterion does not seem to fare much better. First, in the appropriate context any part of speech can be a subject or a predicate. For example, the preposition 'of' or the negation 'not,' which are certainly obvious candidates for being regarded as syncategorematic, can be used as subjects in the sentences '*Of* is a preposition' and '*Not* is a negation,' where they are taken to stand for themselves (and other token phrases of the same type) or, as medieval logicians would put it, in 'material supposition.' (Cf. the modern distinction between mention and use.) Accordingly, later medieval authors sometimes refined the syntactic criterion by adding the requirement that syncategorematic terms are those that cannot be subjects or predicates when used 'significatively' (i.e., in their proper function) and not with the intent to take them for themselves. However, this refinement clearly indicates that the distinction primarily applies not to words per se but, rather, to their different uses. This point is further reinforced by the fact that parts of speech that on the simple syntactic criterion would be deemed syncategorematic in some of their uses can be subjects or predicates even when taken significatively. For instance, adjectives that cannot serve as subjects on their own can be predicates (e.g., contrast the grammatical 'A man is brave' with the ungrammatical 'A brave is a man'), and they can have substantive uses (in Latin marked by the neuter gender),

in which they can even serve as subjects (as in the Latin sentence, *Album est coloratum* '[What is] white is colored,' but even in English we can say, 'Blue is a soothing color'). Furthermore, logicians, who were primarily interested in the semantic features of syncategoremata, would not regard adjectives and adverbs as syncategorematic without further ado.

Therefore, to distinguish such terms from syncategoremata pure and simple, they introduced a further distinction. The two most influential authors of the 13th century on this topic, William of Sherwood and Peter of Spain, both distinguished 'pure categoremata' (i.e., subjects and predicates) from their dispositions or determinations (Peter of Spain, 1992: 38–41; William of Sherwood, 1941: 48). However, they also distinguished those dispositions of subjects and predicates that belong to them insofar as they are subjects and predicates (such as 'signs of quantity,' i.e., quantifiers), the pure syncategoremata, and those dispositions that belong to the things that are signified by subjects and predicates regardless of the fact that they are subjects and predicates. The latter are just categorematic dispositions of pure categoremata, such as adjectives and adverbs. For example, in the proposition 'Every wise man is running,' the pure syncategorematic term 'every' is a determination of the subject term of this sentence in relation to the predicate, determining that the sentence is true only if the predicate applies to everything that falls under the subject. Thus, 'every' applies to the subject insofar as it is the subject of the predicate of this sentence. However, the determination 'wise' pertains to 'man' regardless of what the latter is subjected to and how. This determination merely determines that of all man only the wise are considered (i.e., those things that have the property signified by the adjective).

Thus, adjectives and adverbs, even in their purely adjectival or adverbial uses, on this criterion are no longer regarded as pure syncategoremata, even if they cannot be self-standing subjects or predicates. Rather, they are regarded as categorematic parts of complex subjects and predicates signifying the dispositions of the things signified by nouns and verbs, the principal parts of such complex subjects and predicates.

Further refinements of the distinction were provided by the nominalist philosophers of the 14th century (see **Nominalism**), such as William Ockham, John Buridan, and Albert of Saxony, with reference to their conception of a 'mental language,' a natural system of representation constituted by mental concepts, the mental acts of a human mind to which spoken or written parts of speech are systematically subordinated, rendering these spoken or written signs

meaningful (*see Mentalese*). In this setting, any part of a spoken or written language is said to signify immediately the concept to which it is subordinated, and it is said to signify ultimately the object or objects conceived by means of the concept to which it is subordinated (Buridan, 2001: xxxiv–xli). However, since some concepts have only the function of combining simple concepts into complex ones (e.g., a mental copula or conjunction), or just to modify the representative function of other concepts (e.g., a mental term-negation), but in themselves do not have the function of representing any objects, such concepts themselves are syncategorematic in mental language. Thus, the purely syncategorematic terms of spoken or written languages will be those that are subordinated to such syncategorematic concepts.

For example, as Buridan (2001: 234) remarks,

The copulas ‘is’ and ‘is not’ signify different ways of combining mental terms in order to form mental propositions, and *these different ways [of combining] are in their turn complexive concepts*. . . . And so also the words ‘and,’ ‘or,’ ‘if,’ ‘therefore,’ and the like designate *complexive concepts* that combine several propositions or terms at once in the mind, but nothing further outside the mind. These words are called purely syncategorematic, because they signify nothing outside the mind, except along with others, in the sense that the whole complex consisting of categorematic and syncategorematic words does signify the things conceived outside the mind, but this is on account of the categorematic words.

Buridan’s younger contemporary, Albert of Saxony (1974: f. 2v), provides further clarification of what we should understand by the significative function of syncategorematic terms when he observes:

If the terms ‘every,’ ‘no,’ etc. are taken materially, then they certainly can be subjects or predicates of propositions, as when we say ‘Every is a universal sign,’ or ‘Or is a [disjunctive] conjunction,’ or ‘No is an adverb,’ or ‘And is a copulative conjunction.’ For in these propositions these words are not taken significatively, since *they do not exercise the function [non exercent officium] which they were imposed to exercise*. So, in the proposition ‘Every is a universal sign,’ ‘every’ does not distribute anything, in ‘No is an adverb,’ ‘no’ does not negate anything, and likewise, in ‘And is a copulative conjunction,’ ‘and’ does not copulate anything; therefore, in these propositions these terms are taken not syncategorematically, but categorematically.

Therefore, syncategorematic terms, when they are taken significatively, are imposed to exercise the logical functions of modifying the semantic functions of categorematic terms with which they are construed on account of being subordinated to mental acts that exercise these functions on the mental level. Indeed, as Albert of Saxony (1974: f. 3r) notes, this is

precisely the reason why in their significative function they cannot be subjects of predicates. Thus, Albert presents the semantic distinction on the mental level as the ultimate reason for the syntactic criterion of the distinction on the spoken level. Indeed, later medieval treatises (in the late 14th and early 15th centuries) on concepts and mental language, such as those by Thomas of Cleves, Paul of Gelria, or Peter of Ailly, draw the distinction as pertaining directly and primarily to acts of the mind. These authors describe ‘mental categoremata’ as being acts of conceiving of some objects, as opposed to ‘mental syncategoremata,’ which are rather different modes or ways of conceiving of the objects conceived by the former (Bos and Read, 2001: 14, 54–57, 96, 130; Peter of Ailly, 1980: 18–19; see also the previous quote from Buridan). From this characterization, and from the common medieval doctrine that the semantic functions of spoken and written terms are determined by the semantic functions of the concepts to which they are subordinated, we get as a simple corollary the usual semantic and syntactic features of (pure) syncategoremata, namely that they are cosignificative rather than significative on their own, and that taken significatively they cannot be referring terms of propositions.

Although the distinction drawn in these terms was not in vogue in early modern philosophy, it is significant that John Locke would characterize the parts of speech he calls ‘particles’ (but that his medieval colleagues would recognize as syncategoremata) as being “marks of some action or intimation of the mind” – that is, some mental operation on ideas of the mind (Locke, 1995: bk. IV, c. 7, n. 4). Later, Immanuel Kant would describe pure concepts of understanding as ‘logical functions,’ directly preparing the way for Gottlob Frege to describe quantifiers as ‘second order concepts’ (i.e., as concepts operating on concepts).

Philosophical Significance of the Distinction

Syncategorematic terms present a particular problem for those philosophers who would take the primary function of elements of a language to be the signs or names of things. For in the case of syncategorematic terms, we just do not seem to have obvious candidates among things in the world for these terms to name. Nevertheless, medieval realists, such as Peter of Spain or William of Sherwood, or the modistic grammarians of the 13th and 14th centuries, such as Thomas of Erfurt (for further references, see Zupko, 2003), who professed a close parallelism between *modi significandi* (modes of signifying), *modi intelligendi*

(modes of understanding), and *modi essendi* (modes of being), assumed in their ontology certain modes of being or dispositions of things corresponding to the modes of signifying determined by modes of understanding conveyed by syncategorematic terms. Therefore, in this framework, syncategorematic terms do have counterparts in reality: the modes or dispositions of things that ‘prompt’ us to conceive of and hence signify things in certain ways.

Although these philosophers, logicians, and grammarians were careful to attach only a certain diminished degree of reality to these dispositions, nevertheless, it was precisely their ‘ontological liberalism’ that prompted William Ockham and his nominalist followers discussed previously to identify syncategoremata primarily with the mental acts modifying the representative function of categorematic concepts. For in this nominalist framework, syncategorematic terms simply have no extramental counterparts: the complex expressions they form with categorematic terms signify only the things signified by the categorematic terms, but in different ways. Thus, for example, as Buridan explicitly concluded, the proposition ‘God is God’ and the proposition ‘God is not God’ signify extramentally exactly the same thing as the term ‘God’ does, but this does not render these expressions synonymous; they signify the same thing differently because of the different syncategoremata signified by them in the mind (Buridan, 2001: 234). This is how late-medieval nominalists were able to have a parsimonious ontology along with a sufficiently ‘fine-grained’ semantics, by making the necessary semantic distinctions on the conceptual and not on the ontological level.

In addition to these and similar ontological considerations, the reinterpretation of the medieval distinction had even more far-reaching consequences in early modern and modern philosophy with Kant’s reclassification of a number of traditional metaphysical concepts, such as substance and accident, cause and effect, existence, necessity, and possibility, as concepts of pure understanding – that is, as logical functions or syncategoremata. Kant’s considerations, especially those concerning existence, directly paved the way for Gottlob Frege’s analysis of the notion of existence as a second-order concept, the existential quantifier, which in turn could immediately be exploited by the anti-metaphysical program of logical positivists, such as Rudolf Carnap (1959). Accordingly, without the recent reevaluation of the concepts of existence, possibility, and ontological commitment in the framework of modern possible-worlds

semantics, metaphysics probably still could not be regarded as the legitimate philosophical subject in analytic philosophy it has become in the past few decades. As even this example shows, our actual understanding of the medieval distinction still has fundamental significance in our considerations concerning the relationships between language, thought, and reality.

Syntax–Semantics Interface

J-P Koenig, University at Buffalo, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

‘Syntax’ in this article refers to the organization of the words in a sentence and to the set of rules or constraints that organize words into sentences. ‘Semantics’ refers to the meaning of words and sentences and to the rules or constraints by which the meanings of sentences are built from the meanings of words. It is widely believed that the ability to combine words (and morphemes) to build more complex meanings from these syntactic combinations is a hallmark of human languages. Modeling this ability is one of the central aims in linguistics. The study of this ability is the study of the interface between syntax and semantics, and answers to this question distinguish the major current theoretical frameworks.

The Model of Perfection: Artificial Languages

To understand the issues that have occupied researchers, it is useful to compare natural languages with artificial or formal languages: Whether or how natural languages differ essentially from artificial languages helps classify current views. Artificial or formal languages are typically explicitly designed to be ‘perfect’ in the following sense. For each way of combining two or more syntactic expressions, there corresponds a unique way of combining the meaning of the expressions that are syntactically combined. Technically, an isomorphism can be defined between the syntactic and semantic components of formal languages. As a result, the meaning of formulas of arbitrary complexity is easily and unambiguously read from their syntactic surface organization. The formal language used to express referring expressions in arithmetic provides a simple example of this ‘perfection.’ The following are the syntactic formation rules for addition and multiplication.

- Syntactic rule 1: Number names and number variables are syntactically well-formed expressions called terms.
- Syntactic rule 2: If a and b are syntactically well-formed expressions, so is $\lceil a + b \rceil$.
- Syntactic rule 3: If a and b are syntactically well-formed expressions, so is $\lceil a * b \rceil$.

To each of these syntactic rules there corresponds a well-defined semantic rule.

- Semantic rule 1: Terms refer to numbers.
- Semantic rule 2: A formula of the form $(a + b)$ refers to the sum of the referent of a and the referent of b .
- Semantic rule 3: A formula of the form $(a * b)$ refers to the product of the referent of a and the referent of b .

The one-to-one correspondence between the syntactic rules and the semantic rules unambiguously indicates which computations are needed to obtain the referent of an expression of any complexity. Arithmetic expressions wear the needed computations to derive their referents on their sleeves, so to speak. As the two trees in Figure 1 informally depict, we can establish a one-to-one correspondence between syntactic computations and semantic computations. Such correspondences are known as homomorphisms or isomorphisms between syntax and semantics, depending on whether two different syntactic rules may or may not have the same semantic import. Only homomorphisms are relevant for natural languages.

The hypothesis that the interface between natural languages’ syntax and semantics works like that of formal languages goes back to the German mathematician Gottlob Frege (although it is not clear that Frege held that view; see Pelletier, 2001). Frege’s principle, the principle of compositionality, is defined as:

Principle 1. Compositionality Principle (Frege’s principle): The meaning of an expression is a function of the meaning of its parts and the way the parts are combined.

More operationally, since Montague (1974), the principle is understood to mean that we can establish a one-to-one correspondence or homomorphism between syntactic and semantic operations (see Janssen, 1997, for a good review). The models of the interface between the syntax and semantics of natural languages that have been proposed in the last 30 years can be profitably categorized on the basis of:

Figure 1 The parallel between (A) syntactic composition and (B) semantic composition in the language of arithmetic.

1. Whether they claim that natural languages differ **essentially** from the language of simple arithmetic formulas, that is, whether there is a homomorphism between the syntax and semantics of natural languages.
2. Whether the claimed correspondence (if any) must exist between syntactic **rules** and semantic **rules** (as Montague originally claimed) or between the syntactic and semantic **structures** that these rules output.

Where Natural Languages Seem Imperfect

Interfacing syntax and semantics would become a rather trivial task if natural languages' syntactic rules/constraints/structures paired with their semantic rules/constraints/structures as straightforwardly as in the case of the language of simple arithmetic. If natural languages are as 'perfect' as the language of simple arithmetic, they are not obviously so. Thus, claiming that there is no 'important theoretical difference' between formal and natural languages, as Montague (1974: 188) did, is a bold and noteworthy claim. Below are sentences that illustrate some of the mismatches (the 'imperfections') typical of natural languages. Discussions of how to appropriately model the interface between the syntax and semantics of these and similar classes of sentences has occupied much of the literature in the last 30 years.

(1a) It seems that John is tired.

(1b) John seems to be tired.

(2a) Who(m) did John see?

(2b) Jean a vu qui?
Jean has seen who(m)

(3a) Everyone loves someone.

(3b) $\exists x(\text{human}'(x) \wedge (\forall y(\text{human}'(y) \rightarrow \text{love}'(y, x)))$

(3c) $\forall y(\text{human}'(y) \rightarrow \exists x(\text{human}'(x) \wedge (\text{love}'(y, x)))$

(4a) Mary played.

(4b) Mary will play.

(5a) Mary began the beer.

(5b) Mary enjoyed the novel.

Sentence (1b) is an example of what is called (subject-to-subject) raising and, at least at a coarse level of analysis, is truth-conditionally equivalent to (1a). In both cases, the referent of *John* is the semantic argument of the meaning of the VP (*be*) *tired*; but only in sentence (1a) is *John* the subject of that VP. A consequence of this common semantics but distinct syntax is that the same combination of a subject and a VP does not seem to always have the same semantic import. In the case of the embedded clause of sentence

(1a), that syntactic combination means the application of the VP meaning to the subject's meaning; in the case of *John* and *seems to be tired* in sentence (1b), it appears that it does not because the referent of *John* does not appear to be a semantic argument of the meaning of *seems to be believed*. In other words, more than one semantic function might correspond to the combination of an NP and a VP.

The second example's relevance is slightly different. Let us assume that the meanings of questions expressed by sentences such as (2a) can be represented as in (6).

(6) for which animate x , John saw x

Then the surface structure of (2a) mirrors the semantic structure of (6). But the surface structure of the corresponding French sentence in (2b) (and other interrogative utterances in *in situ* languages) does not mirror its semantic structure (assuming that the semantics of English and French questions is the same). The difference is most easily seen in Figure 2. The syntactic position of *who* matches the semantic position of its translation in (6). Syntactically, *who* takes as its right sister a tree whose root is labeled S (its syntactic scope); semantically, the denotation of *who* is an operator that takes a propositional function as operand (its semantic scope). But *qui*, which is embedded within the verb phrase in French does not match its semantic scope (at least on the surface). No homomorphism seems to exist between syntactic and semantic structures for *in situ wh*-questions (although a homomorphism might still exist between syntactic and semantic rules).

Sentences such as (3a) have been at the center of many theories of the interface between the syntax and semantics of natural language. Such sentences are semantically ambiguous. According to one reading, there is at least one person that everybody loves, say *Gandhi*. Another reading is one in which, for each individual, there is at least one person he or she loves, but not all individuals need love the same entity; to each his or her own loved ones. The two first-order predicate logic formulas in (3b) and (3c) represent these two distinct readings. (*Everyone* and *someone* are understood here as equivalent to *every x that is*

Figure 2 The difference between (A) English-style and (B) French-style questions.

human and *some x that is human*; *human'*, *love'* and *other'* expressions represent the meaning of the corresponding English words.) If we believe that these different readings correspond to different meanings of sentence (3a) (an assumption which may be challenged; see later discussion), sentences such as (3a) seem to contravene the claim that natural languages are ‘perfect’ because (3a) appears to have only one syntactic structure. We thus, have at least two semantic functions for combining a quantified direct object with the verb: one in which the semantic output is such that the subject has wide scope over it and one in which the semantic output does not force the subject to have wide scope over it. Contrary to the homomorphism hypotheses, there does not seem to be a unique semantic rule for every grammatical combination (here, the combination of verbs and direct objects).

The sentences in (4) exemplify the same problem as the sentences in (2) but within a single language. Under the assumption that, semantically, tense operators take propositions or event descriptions as operands (see Dowty, 1979; de Swart, 1998), the morpho-syntactic structure of (4a) does not match its semantic structure (even leaving aside the occurrence of the subject outside the verb phrase). The morpho-syntactic expression of the tense operator is a suffix on a word (the verb *play*), whereas its semantic translation takes a full event description or proposition as argument – something typically expressed as a VP or clause – as informally shown in (7).

(7) TENSE [EVENT DESCRIPTION/
PROPOSITION]

Example (4b) shows that English is not only ‘illogical,’ it is not systematic, in that the same semantic function (tense operators) can be expressed as an independent word that takes a verb phrase as complement or as a suffix on the verb.

Finally, example (5) illustrates that what is literally expressed does not provide all the intuitive semantic content we ascribe to utterances. What Mary began in (5a) is *drinking the beer* and in (5b) *reading the book* (possibly *writing the book*). Semantic content seems to have to be interpolated between the semantic translation of the verb and the semantic translation of the direct object, a phenomenon dubbed ‘coercion’ in the computational semantics literature (Moens and Steedman, 1988; Pustejovsky, 1995).

Theories of the Syntax–Semantics Mismatch

Existing grammatical frameworks make different hypotheses about how the syntactic–semantic mismatches

mentioned in the previous section can be resolved and about how artificial languages’ perfection is reflected in natural languages. We can distinguish at least three general hypotheses; each is currently actively being explored.

- Hypothesis 1. Deep Split Structural Isomorphism (DSSI): Natural languages’ imperfection is true of the surface syntactic structure of sentences. But strings can be assigned different structures at different levels of representation, and, for each kind of semantic relation, there is at least one level at which syntactic structures match very closely (if not entirely) the relevant aspects of semantic structures.
- Hypothesis 2. Natural Language Perfection (NLP): Natural languages’ imperfection is only apparent. A single semantic combination rule can in fact be assigned to every combination of syntactic expressions (although the syntactic category of natural language expressions might then need to be flexibly assigned).
- Hypothesis 3. Imperfections Reflect the Architecture of Grammars (IRAG): Natural languages’ imperfection is the result of their architecture (or even the architecture of the mind). Syntax and semantics are independent generative systems that are related through correspondence rules. Although there are regularities in how structures generated by one system are related to structures generated by the other, no homomorphic relation can be expected.

Proponents of these hypotheses typically focus on distinct subsets of the mismatches mentioned in the previous section. The DSSI hypothesis, for example, which goes back at least to the 1960s (see Lakoff, 1971), does not focus on coercion phenomena. The IRAG hypothesis, on the other hand, does not focus on quantifier scope mismatches. How easily each approach can tackle the **entire** set of mismatches or even whether they should (i.e., whether these mismatches form a natural class) is unclear at this point. This section focuses on the mismatches that each hypothesis models and, in particular, those mismatches whose analyses are easiest to present briefly.

The Deep Split Structural Isomorphism Hypothesis

The descriptive import of the DSSI hypothesis is most easily seen in typical analyses of examples (3a) and (4). Maintaining the DSSI hypothesis in the face of these surface mismatches leads to the claim that sentence (3a) has two distinct syntactic structures at the LF level of representation (often called L(ogical)-F(orm)), but a single syntactic structure at another level (often called s-structure) (see May,

1985; see Chomsky, 1995, and subsequent work in the Minimalist Program for a slightly different, but conceptually similar, model of these phenomena). Technically, these distinct structural analyses are generated by using two sets of rules, a set of context-free rules (e.g., those in (8) for sentence (3a)) and one or more additional (transformational) rules such as that in (9). In (8), the notation $\text{NP}[\pm Q]$ is used as a variable to range over all NPs, whereas $\text{NP}[+Q]$ ranges over only NP quantifiers. In (9), t_i is a placeholder that indicates where the NP quantifiers moved from and is called a trace. (These rules are adapted from Chierchia and McConnell-Ginet, 2000.)

- (8a) $S \rightarrow \text{NP}[\pm Q]\text{VP}$
 (8b) $\text{VP} \rightarrow \text{V NP}[\pm Q]\text{VP}$
 (8c) $\text{NP}[+Q] \rightarrow \text{Det N leveryone|someone}$
 (8d) $\text{Det} \rightarrow \text{every|a}$
 (8e) $\text{N} \rightarrow \text{man|woman}$
 (8f) $\text{V} \rightarrow \text{loves}$
 (9) $[_S \dots \text{NP}[+Q] \dots] \Rightarrow [_S \text{NP}[+Q]_i [_S \dots t_i \dots]]$

The context-free rules in (9) generate the single s-structure-level syntactic tree in Figure 3. Subsequent applications of the transformational rule in (9) results in the two LF-level syntactic trees in Figures 4 and 5, depending on which of the $\text{NP}[+Q]$ is targeted first. The two relevant readings of sentence (3a) now

Figure 3 The s-structure representation of sentence (3a).

Figure 4 LF structure for the wide-scope existential reading of sentence (3a).

receive two distinct representations at one level of representation, and the homomorphism principle can be maintained if we assume the semantic interpretation of sentence (3a) is read from its LF representations. (Strictly speaking, homomorphisms require that ‘operations’ be defined in both domains put into correspondence, e.g., syntax and semantics. Thus, the output structures for which an homomorphism exists must be reanalyzed in terms of a local tree-building operation. Alternatively, the notion of order-homomorphism between structures outputted by the grammatical rules can be used, the relevant order being here tree-inclusion; see Cohn, 1981.) Compare the relative depth of embedding of the two quantified NPs in Figures 4 and 5 with that of the corresponding quantifiers in the first-order predicate logic formulas for the two readings of sentence (3a) in Figures 6 and 7.

The distinction in morpho-syntactic encoding that tense morphemes receive both within English and crosslinguistically is subject to a similar kind of analysis for proponents of the DSSI hypothesis. The homomorphism hypothesis can be maintained because a single surface expression can have two different structures at two distinct levels of representation. In particular, tense can have syntactic scope over the structure that denotes an event description (or

Figure 5 LF structure for the narrow-scope existential reading of sentence (3a).

Figure 6 A tree representation of the wide-scope existential reading of sentence (3a).

proposition) at one level of representation (the d-structure, or its equivalent in the Minimalist Program) but not at another level of representation. The common structure of sentences (4a) and (4b) at the d-structure level is represented in Figure 8.

The distinct surface expression of the morpheme encoding tense in sentences (4a) and (4b) follows from operations similar to the transformational rule in (9) and the assumption that these operations are sensitive to the distinction between affixes such as *-ed* and free morphemes such as *will*. The contrast in the encoding of time in English is only the tip of the iceberg. Different tenses and various aspect markers may vary in their surface expression within a single language and across languages. The strategy just outlined can be applied generally to all these cases (see Cinque, 1999, for one of the most detailed explorations of this possibility).

Similar accounts are provided for the data set in (2). More generally, the claim that ‘deep down’ the interface between syntax and semantics is more transparent than what surface strings suggest requires providing each surface string with several distinct syntactic analyses:

- An analysis that allows predicate–argument relations (including predicate–argument relations of tense, aspect, and modal operators) to be homomorphically read from the syntactic tree (e.g., an analysis that reads the tense predicate/VP argument relation from the syntactic structures of trees such as the one in Figure 8, i.e., from structures before verb stems move).

Figure 7 A tree representation of the narrow-scope existential reading of sentence (3a).

Figure 8 The d-structure representation of sentences in (4).

- An analysis that allows quantifiers and other scoping relations that do not involve a predicate–argument relation (focus vs. ‘presupposed,’ topic vs. comment, and so forth) to be homomorphically read from another syntactic tree (e.g., an analysis that reads the quantifier/scope relation from the syntactic structure of trees such as the ones in Figures 4 and 5 i.e., from structures that result from moving the NP quantifiers.)
- An analysis that represents the structure of the surface string.

To mediate among these analyses, successive applications of a general rule similar to (9) is posited. Morphemes, words, or phrases whose semantic interpretation contravenes their surface syntactic position must be moved to or from a position where the semantic interpretation of the local syntactic structure that they participate in can be easily read. For example, to account for the event description or propositional nature of the semantic argument of the past tense operator in sentence (4a), the past tense morpheme takes as syntactic complement at d-structure a structure that includes the verb stem for *play*, in conformity with its semantic constituency; subsequent movement of the verb stem ensures that it combines with the syntactically higher affix to form the surface verb form *played*. Similarly, the quantifiers *everyone* and/or *someone* in sentence (3a) are assumed to ‘covertly’ move to a position in which their semantic scope is easier to read from the local tree they are part of. As a result, the syntactic notion of hierarchical superiority (or c-command) matches the semantic notion of wide scope (at least in the traditional first-order predicate calculus representation of scope dependencies). Note that, the mapping of syntactic tree configurations onto semantic configurations must precede the movement operation in the case of the movement of the verb stem, but must follow the movement operation in the case of the movement of quantifiers. (Alternatively, the syntax-to-semantics mapping targets the position of the moved constituent, or head of a chain in the sense of Chomsky, 1981, for quantifiers, but targets the position of the trace of the moved constituent for verb stems and raised NPs such as *John* in (1b).)

In theories that follow the just-outlined general model of the interface between syntax and semantics, one syntactic structure can be provided from which the relevant part of semantic representations can be homomorphically read. But, there is no **single** such structure, a state of affairs that is seen by some as effectively abandoning the spirit of Frege’s compositionality principle (Jacobson, 2002). But, proponents of the DSSI hypothesis have stressed that the kind of

	loves	someone
	$(S \backslash NP) / NP :$	$(S \backslash NP) \backslash ((S \backslash NP) / NP) :$
	$\lambda y \lambda x.(\text{love}'(x, y))$	$\lambda q. \exists y(\text{human}'(y) \wedge q(y))$
Everyone	FA	
$S / (S \backslash NP) :$	$S \backslash NP :$	
$\lambda p. \forall x(\text{human}'(x) \rightarrow p(y))$	$\lambda x. \exists y(\text{human}'(y) \wedge (\text{love}'(x, y)))$	FA
$S :$		
$\forall x(\text{human}'(x) \rightarrow \exists y(\text{human}'(y) \wedge \text{love}'(x, y)))$		

Figure 9 Derivation of the semantic representation of the narrow-scope existential reading of sentence (3a).

structural operations and configurations necessary to model sentences such as (3a) or (4) are at play in syntactic processes that do not bear on the interface between syntax and semantics. Strictly syntactic constraints might thus provide independent evidence for the semantically more complex DSSI hypothesis (see May, 1985; Hornstein, 1995). Whether the adduced similarities between strictly syntactic constraints and the operations/structures presented in this section are sufficient to weaken Frege's principle remains a subject of debate.

The Natural Language Perfection Hypothesis

Hypothesis 2 answers the interface challenge by denying that natural languages have any real imperfections or that natural languages relate their syntax and semantics in a qualitatively distinct manner from artificial languages. The impression of imperfection comes merely from too simple a view of the rules available to combine natural language expressions and the erroneous reification of the notion of syntactic constituent structure. The compositionality of natural languages, in this view, pertains to the pairing of a set of semantic and syntactic rules (the rule-to-rule hypothesis of Bach, 1976), not to a pairing of the structures that these rules output. In contrast to the DDSI hypothesis, the NLP hypothesis claims that the homomorphism between syntax and semantics need not be split into two partial homomorphisms (to infer from surface expressions predicate–argument relations and operator–scope relations). It also claims that the syntax–semantics correspondence is best understood in terms of syntactic and semantic rules rather than between syntactic and semantic structures (local tree configurations, *modulo* the previously mentioned caveats). The NLP hypothesis goes back at least to Montague's work. It has been adopted by several different theories (e.g., Klein and Sag, 1985; Steedman, 2000; Copestake *et al.*, 2001); it is the hallmark of the Categorical Grammar/Lambek Calculus tradition. Steedman (2000) provides one of the most articulate versions of this approach. In his analysis of example (3a), as is common to all approaches

that assume that the translation from syntactic structure/categories to semantic structure/categories is local (the rule-to-rule hypothesis), each expression is assigned both a syntactic and semantic category, and each combinatorial rule affects both the syntactic and semantic categories of the expressions it combines. Syntactically, *loves* is taken to be a functor that must combine with a direct object NP to its right and a subject NP to its left to form a sentence. This syntactic subcategorization is written $(S \backslash NP) / NP$. For illustrative purposes, quantified NPs such as *everyone* and *someone* are treated syntactically as either NPs or functors that must combine with a VP to their right to form a sentence or with a verb to their left to form a VP. This second syntactic subcategorization is written $S / (S \backslash NP)$ and $(S \backslash NP) \backslash ((S \backslash NP) / NP)$, respectively. Semantically, *love* denotes a predicate missing two arguments, and *everyone* and *someone* denote predicates missing one argument each. Making use of λ -abstraction to model unsaturated argument positions, the meaning of *love* can be represented as:

$$\lambda y. \lambda x. \text{love}'(x, y)$$

and that of *everyone* and *someone* as

$$\lambda p. \forall x(\text{human}'(x) \rightarrow p(x))$$

and

$$\lambda q. \exists y(\text{human}'(y) \wedge p(y))$$

respectively. Three principles of combination are relevant to modeling sentences (3a) (a few more universal principles, plus language-specific constraints on these principles, are the only other things that are needed to model the interface between the syntax and semantics of natural languages, according to this view):

- Function application, the combination of an argument/complement and a predicate/functor: Combining (in that order) x and $y \backslash x$ or y / x and x yields a y .
- Type-raising, making an argument/complement into a predicate/functor: An expression of category x can be assigned to the category $y / (y \backslash x)$ or $y \backslash (y / x)$.

Everyone	loves	
$S/(S\backslash NP) :$	$(S\backslash NP)/NP :$

FA		
$S :$		
$\exists y(human'(y) \wedge (\forall x(human'(x) \rightarrow love'(x, y))))$		

Figure 10 Derivation of the semantic representation of the wide-scope existential reading of sentence (3a).

- Function composition, composing two functors: Combining (in that order) two functors x/y and y/z yields x/z .

The derivations of the two relevant readings of sentence (3a) are given in **Figures 9** and **10**. (For ease of exposition, type-raising operations are assumed to have applied in the lexicon and are not represented.) The interpretation of sentence (3a) in which the existential quantifier has narrow scope over the universal quantifier follows from two uses of function application (FA in **Figure 9**; standard steps that simplify the resulting semantic formulas are omitted). The interpretation of sentence (3a) in which the existential quantifier has wide scope over the universal quantifier follows from the use of function composition first and then the use of functional application (FC and FA in **Figure 10**).

The two possible derivations of sentence (3a) outlined in **Figures 9** and **10** clearly obey Frege's principle and the rule-to-rule hypothesis. To each syntactic combination of two of its substrings corresponds a unique combination of the semantic representations of those two substrings. Leaving aside a few additional complexities, modeling the other mismatches previously mentioned, takes a similar form under this view. Alternative derivations (leading to either distinct surface expressions of the same semantic content or distinct semantic content for the same surface expressions) stem from the (at times nondeterministic) interaction of a handful of combinatory principles (function application, various forms of function composition, and type-raising). Proponents of the NLP hypothesis, thus, provide rule-based, truly compositional models of the interface between syntax and semantics. Whether operations posited by such models, like the operations/structures posited by DSSI models, have independent, purely syntactic justifications remains controversial.

The Imperfections Reflect the Architecture of Grammars Hypothesis

The IRAG hypothesis, which is more recent and less fleshed out than the previous two hypotheses, takes

the interface challenge to reflect a deep truth about the architecture of natural languages (if not the mind). In this view, natural languages are 'imperfect' because each level of analysis (syntax and semantics) has its own 'agenda,' so to speak, and although these 'agendas' are typically aligned, they need not be. The analysis of the sentences in (5) given in Jackendoff (1997) (see also Sadock, 1991, for an early proposal) best illustrates this hypothesis. The context-free rules in (8) account for the (simplified) syntactic structure of sentence (5a), as shown in the tree in **Figure 11**.

Two sets of correspondence rules link the syntactic structure diagrammed in **Figure 11** or that of the more explicit expression of its content in sentence (10a) and their common semantic representation. (*Begin* is assumed here to denote a two place predicate whose two arguments are an actor and a type of action; informally, $BEGIN'(x \text{ actor}, y \text{ action})$.)

(10a) Mary began drinking the beer

(10b) Mary began reading the book

The rules for interpreting the more explicit versions of sentences (5) in (10) are informally formulated as follows.

1. Interpret *begin* as $BEGIN'$.
2. Interpret the denotation of (definite) direct object NPs as semantic arguments of the denotation of verbs.
3. Interpret VP complements of verbs as denoting action arguments of the interpretation of verbs.

To model the 'nondefault' correspondence between the syntactic relation of the verb and its direct object and their semantic relation in sentences such as (5), Jackendoff posits rule 4 as an alternative to rule 2.

4. Interpret NP as $F(Int(NP))$ (i.e., as the unspecified activity denoted by F and involving the interpretation of NP).

The application of rules such as rule 4 must be further constrained so as to not apply in the 'default' case (see Sadock, 1990, for suggestions and Jackendoff, 2002, for more details).

Figure 11 The syntactic structure of sentence (5a).

The IRAG hypothesis resembles the DSSI hypothesis in claiming that syntactic structures are linked to semantic structures (*modulo* the previously mentioned caveats) and that correspondence rules take the form: Configuration X in syntax corresponds to configuration Y in semantics. But it views the assumption that semantic structures can **always** be read from syntactic structures (as in the DSSI hypothesis) or the syntactic formation rules that have applied (as in the NLP hypothesis) as an illusion created by the existence of default correspondence rules. The IRAG hypothesis also resembles the NLP hypothesis in positing a direct pairing of syntactic and semantic types (NPs and $F(\text{Int}(\text{NP}))$ in rule 4, or the syntactic category and meaning of lexical items). But it insists that syntax and semantics are independent generative systems that derive their outputs on their own, and thus it views mismatches not as illusions but as evidence for this architectural independence or representational modularity (Jackendoff, 1997).

Shaking Things Up

How Specified Is Grammatical Meaning?

All the approaches discussed in the previous section presume that grammatical meaning (the output of interfacing the syntactic and the semantic components of a grammar) is a message whose content is similar to a logician's proposition (or its conceptual equivalent). The relevance of some of the examples in (2)–(5) to models of the interface between syntax and semantics depends on this presumption. Consider example (3a). The existence of one surface syntactic structure but two readings for this sentence is part of what motivates the DSSI hypothesis and the postulation of multiple syntactic levels of representations. Similarly, the two sequences of rules deriving the two readings of sentence (3a) sketched in Figures 9 and 10 presuppose that these two readings are the output of interfacing syntax and semantics. Examples of coercion such as (5) are only relevant to the uncovering of the architecture of grammar if the addition of the

'missing' material is believed to be a grammatical matter. If it is not, grammatical nondefault correspondence rules of the kind that rule 4 exemplifies are not needed to rectify the mismatch.

Recent work in computational semantics challenges traditional assumptions about the semantic output of grammars and, as a consequence, has altered the relevance of some of the examples in (2)–(5). A fair amount of work, in particular, challenges the view that the semantic output of grammar rules or constraints is fully specified and argues that this output is underspecified. (Cooper, 1983, is a precursor of that computational work. Philosophers of language and neo-Gricean semanticists have also challenged this view, e.g., Recanati, 1993; Levinson, 2001; some of their conclusions parallel those drawn by computational semanticists.) Two main areas of research have focused on whether scopal relations in sentences such as (3a) are grammatically underspecified and whether semantic type mismatches such as in (5) are resolved grammatically. The results of this research are:

- Many scopal relations may not be determined by grammatical rules or constraints, and their determination might involve postsemantic processes.
- The syntactic relation between a head and a complement (e.g., a verb and its direct object) may not correspond semantically to the relation between a predicate and an argument (even leaving aside quantificational NPs). The corresponding semantic relation may be indirect, as, for example, the relation between a predicate and an argument of an argument of ... an argument.

The difference between underspecified and fully specified semantic representations can be illustrated using tree diagrams. A fully specified semantic representation can be diagrammed as a set of fully connected trees, as in the case of Figures 6 and 7 for the first-order predicate calculus representations of the two relevant readings of sentence (3a). As discussed earlier, the DSSI hypothesis claims that the relative hierarchical position of the quantifiers in these semantic representations matches that of their syntactic expression at the LF level of analysis (see Figures 4 and 5). Similarly, sentence (11) (a slightly more complex version of (3a)) would receive as **one** of its LF analyses under the DSSI hypothesis the tree configuration in Figure 12.

(11) Every man loves a woman.

Underspecified semantic representations, on the other hand, can be diagrammed as a less than fully connected tree. The semantic output of parsing sentence (11), for example, would be a set of three partial trees, as Figure 13 illustrates.

Figure 12 LF structure for the narrow-scope existential reading of sentence (11).

Figure 14 The syntactic structure of sentence (11).

Figure 13 The underspecified semantics of sentence (11).

Each treelet in **Figure 13** can receive a compositional semantics (alternatively, each rule used to build the treelets can be paired with a semantic rule). The leftmost tree can be interpreted as:

$$\lambda p.(\forall x(\text{man}'(x) \rightarrow p(x)))$$

(the ... in the treelet is translated as a lambda-abstracted variable); the middle tree as:

$$\lambda q.(\exists y(\text{woman}' \wedge q(y)))$$

and the rightmost tree as:

$$\lambda y \lambda x.(\text{love}'(x, y))$$

This is very similar to what proponents of the NLP hypothesis would do: Each such treelet's meaning can be derived through functional application. But the semantic correlate of syntactically combining a verb and its direct object or a VP and its subject is merely the set union of these constituents' meanings. The semantic interpretation of these underspecified meanings is often said to be simply the set of fully connected semantic trees that can be built from these treelets. (Reyle, 1993, provides a possible direct model-theoretic interpretation of underspecified semantic representations.)

Now, because the semantic output of grammars is not a **single** fully connected tree, the structure of the

syntactic tree cannot reflect the structure of the semantic representation. Thus, such frameworks can assume a single syntactic structure as the output of the syntactic component of grammars – for example, the tree in **Figure 14** for sentence (11), given the phrase structure rules in (8) – while maintaining a rule-to-rule hypothesis.

The analysis of sentences that involve coercion follows parallel lines. Egg *et al.* (2001), for example, argued that the semantic interpretation of sentences such as (5) does not include additional semantic material (i.e., the direct object is not grammatically interpreted as *drinking the beer* and *reading the book*). Rather, the semantic output is a partial tree specification. The predicate *begin'* is required to dominate the interpretation of its complement (i.e., to include the interpretation of its complement within its second argument), but is not required to **immediately** dominate it, leaving open the possibility that pragmatic processes will interpolate conceptual content between the two. Nonstandard grammatical correspondence rules such as rule 4, whose sole purpose was to interpolate such conceptual content, would now become otiose.

Where Does the Meaning Come From?

Another assumption of the first two hypotheses we have reviewed is that the nature of the meaning carried by a lexical item differs from that encoded by syntactic structures or rules. Words (or morphemes) carry substantive meanings, whereas syntactic structures or rules only serve to combine or put these substantive meanings together. This division of labor is quite clear in the two derivations of sentence (3a) represented in **Figures 9** and **10**. The meanings of words carry the quantificational and predicative meanings; the rules only fill in the missing arguments in these lexical meanings (providing values for lambda-abstracted variables). Syntactic rules or

structures in such a view do not **carry** meaning; they merely glue or combine meanings carried by words or morphemes.

The last 20 years have seen the emergence of another view that holds that syntactic structures **do** carry meaning, too, at times (see Fillmore *et al.*, 1988; Ginzburg and Sag, 2001, for early and most articulated examples of this line of research). Syntactic structures thus can **both** glue meanings together and/or carry meaning on their own. Convincing evidence that syntactic structures, rules, or constructions carry meaning, is hard to come by because it is almost always possible to assign the meaning assigned to a syntactic construction to some lexical material within the sentence. But Ginzburg and Sag (2001) presented data (see also Huang, 1982) that suggest that syntactic structures do carry meaning. They show that fronting the *wh*-phrase, as English often does, as in (2a), has an effect on meaning. Fronted *wh*-phrases cannot have wider scope than their surface position. In contrast, *wh*-phrases that remain in position are freer in their scoping possibilities. In particular, they can have scope over the matrix clause when a question is embedded after verbs such as *know* and *ask*. The contrast between the Chinese (Mandarin Chinese) sentence in (12) (from Huang, 1982), in which the *wh*-phrase has remained in position, and its two possible interpretations indicated in its English translations illustrates the difference. The English *wh*-phrase has been fronted in both translations, and its scope is determined by its surface position. But the Chinese *wh*-phrase, which remains in place, can vary in scope. The different interpretative possibilities of the Chinese example and its English translations do not seem due to differences in **lexical** meaning between *shei* and its English counterpart *who*. Rather, it seems to follow from the different syntactic structures in which the two words occur (or the operations they undergo), thus suggesting that syntactic structures or rules contribute more to meaning than the glue for (substantive) lexical meanings.

- (12) [Zhangsan [zhidao shei mail-le shu]]
 Zhangsan know who buy-ASP book
 ‘who does Zhangsan know bought books? /
 Zhangsan knows who bought books’

Although much work has been devoted in the last 30 years to developing more precise architectures for the interface between syntax and semantics and finding data that support them, garnering convincing evidence that favors one hypothesis to the exclusion of the others has been hard. The difficulty partly stems from the fact that the proposed models are sufficiently rich to account for most of the data. Choosing among them is, therefore, more a matter

of elegance or some intuitive notion of simplicity than sheer descriptive adequacy. Furthermore, research has often focused on existence proofs (proof that some phenomenon can or cannot be accounted by one (version of) a model) or on relatively small grammar fragments for which explicit syntactic and semantic rules or constraints are provided. Two recent trends suggest better model evaluation might soon be available. First, several researchers now use data on human online sentence processing or word access as additional sources of evidence (see Steedman, 2000; Jackendoff, 2002). Second, large-scale implemented grammars that output both semantic and syntactic representations have developed in the last decade and might therefore allow the large-scale testing of the models on a realistic portion of natural languages, such as the ParGram project within Lexical-Functional Grammar and the LinGO project within Head-driven Phrase Structure Grammar.

Systematicity

P Robbins, Washington University in St. Louis,
St. Louis, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

It is something of a commonplace that linguistic capacities are systematic: very roughly, that understanding a sentence entails understanding certain other sentences related to the first. Likewise, it is something of a commonplace that the best way to account for this fact is by supposing that linguistic meaning is compositional: again roughly, that to understand a sentence, it suffices that one understand the meanings of the words it contains and its syntactic structure. This explanatory hypothesis in turn accounts for much of the reason why compositionality is widely regarded by linguists and philosophers of language as a bedrock constraint on theories of meaning. But the real story about systematicity is rather more complicated. To begin with, the term 'systematicity' is far from univocal. A quick glance at the philosophical literature in which it has figured so prominently in recent years reveals at least three different senses of the term in common use. Since only confusion can result from running these different senses together, we will start by distinguishing them. Then

we will assess the plausibility of various systematicity claims and their broader theoretical significance, giving special attention to the question of compositionality.

Some Varieties of Systematicity

The first and arguably primary notion of systematicity concerns the capacity to process language. More specifically, our linguistic capacity is processing-systematic (p-systematic, for short) if and only if the capacity to understand (know the meaning of) a sentence s in a language L confers the capacity to understand (know the meaning of) a range of sentences $s_1^* \dots s_n^*$ in L such that each s_i^* is structurally related to s in an appropriate way (Fodor and Pylyshyn, 1988; Hadley, 1994; Cummins, 1996). For example, anyone who understands the sentence *John loves Mary* thereby also understands the sentences *Mary loves John*, *John loves John*, and *Mary loves Mary*. The latter three sentences are appropriately structurally related to the first sentence in virtue of the fact that each of the three sentences can be transformed into the first sentence by permuting or substituting co-occurring words of the same grammatical category

(here, the proper nouns *John* and *Mary*). A broader notion of p-systematicity can be arrived at by dropping the co-occurrence restriction, allowing for the substitution of co-categorical words not contained in the initial sentence. Structural relatives of *John loves Mary* in this more liberal sense include, in increasing order of distance, sentences like *John loves Elvis*, *Mary kicks Bridget*, and *Fred bombs Falluja*. The corresponding, stronger p-systematicity claim states that understanding a sentence s confers the capacity to understand a range of sentences $s_1^* \dots s_n^*$ such that each s_i^* is structurally related to s in the sense described above, and each word occurring in s_i^* is contained in the speaker-hearer's lexicon.

According to a second sense of the term, systematicity is a property of language itself, rather than a property of linguistic understanding. Since systematicity of this sort has to do with the expressive power of language, as opposed to the processing power of language users, we'll call it representation-systematicity. The basic idea is analogous to the notion of systematicity with which we began: a language L is representation-systematic (r-systematic) if and only if L can express a proposition p provided that L can express a range of propositions $p_1^* \dots p_n^*$ such that each p_i^* is structurally related to p in an appropriate way (Fodor and Lepore, 1991). The relevant structural relation on propositions can be illustrated with the same examples used above. Assuming L is r-systematic, if the proposition that *John loves Mary* is expressible in L , then so are the trio of propositions that *Mary loves John*, that *John loves John*, and that *Mary loves Mary*. Each member of the trio is structurally related to the initial proposition (that *John loves Mary*) because each can be transformed into the latter by permutation or substitution of co-occurring constituents expressed by words of the same grammatical category. As before, the class of propositions structurally related to the initial proposition can be expanded to include the propositions that *John loves Elvis*, that *Mary kicks Bridget*, and so on, by dropping the co-occurrence constraint on constituents. According to the strengthened r-systematicity thesis, a language can express a proposition p only if it can express a range of propositions $p_1^* \dots p_n^*$, where each p_i^* is structurally related to p in the manner described above, and each constituent of p_i^* is expressible by a word in the language.

Finally, a third notion of systematicity – what we will call grammar-systematicity – also denotes a property of language, but a different property than the one just described. Whereas representation-systematicity is a metasemantic property, grammar-systematicity has a broader metalinguistic scope, encompassing both syntax and semantics. A language L is grammar-systematic

(g-systematic) if and only if s is a grammatical sentence of L provided that any s^* structurally related to s is a grammatical sentence of L (Johnson, 2004). Since the relevant notion of structural relatedness between sentences is the same as that implicated in the definition of processing-systematicity, the same examples will serve. The fact that *John loves Mary* can be transformed without loss of grammaticality by permuting or substituting words of the same category, whether drawn from that sentence or from elsewhere in the lexicon, supports the claim that English is g-systematic.

Claims to the effect that natural language is systematic in any of these three ways – processing based, representation based, and grammar based – have a good deal of face plausibility. But before evaluating such claims, we need to scrutinize the above definitions more closely. In particular, we need to consider what it is for two words to belong to the same grammatical category. Pending some clarification of this issue, the concept of structural relatedness, and with it the very idea of systematicity, will remain somewhat obscure (Johnson, 2004). And a non-circular (i.e., systematicity independent) standard of sameness of category is not easy to formulate. Even the relatively fine-grained category of proper nouns, for example, seems too heterogeneous to support a robust claim of systematicity, as witnessed by the sentence *Julia sang the lead in 'West Side Story'* and its anomalous permutational variant *'West Side Story' sang the lead in Julia*. Given the plurality of constraints – syntactic, semantic, and phonological – on lexical substitution, better candidates for grammatical category-hood are going to be hard to come by (Harris, 1951).

How deep a problem this amounts to, however, depends to some extent on what notion of systematicity one is working with. In the case of grammar-systematicity, for example, the difficulty seems serious enough to warrant skepticism about the substance of the claim that language is g-systematic (Johnson, 2004). Processing-systematicity, on the other hand, is a different story. Since it is impossible to understand an anomalous sentence, it is plausible to suppose that understanding a sentence confers understanding of any structural variant of that sentence, provided that the variant in question is interpretable at all. Similar considerations apply to the case of representation-systematicity (Fodor and Lepore, 1991). It is plausible to suppose that the capacity of language to express a proposition entails the capacity to express any structural variant of that proposition, provided that the variant in question exists and is not anomalous. But this sort of strategy seems to be unavailable in the case of grammar-systematicity. Obviously, it won't do to say 'The structural variants of a grammatical sentence are grammatical, unless they are not.'

Be that as it may, it remains plausible that language is systematic in all three of the ways canvassed above, at least to a modest extent. Consider the following theses:

- *Minimal p-systematicity.* Understanding a sentence *s* entails understanding some structural variants of *s*.
- *Minimal r-systematicity.* If a language *L* can express a proposition *p*, then *L* can express some structural variants of *p*.
- *Minimal g-systematicity.* If *s* is a grammatical sentence, then some structural variants of *s* are grammatical.

Systematicity claims of this sort are hard to resist, given the apparent ease of generalization from the case of *John loves Mary* and its close variants. Whether language is p-systematic, r-systematic, or g-systematic in any stronger sense (e.g., whether ‘many’ can be strengthened to ‘all’) is an open question. But for the purposes of addressing the question of compositionality in natural language, these weak claims are enough to start with.

Explaining Systematicity

The idea that language is compositional, like the idea that language is systematic, can be formulated in various ways (see **Compositionality: Semantic Aspects**). According to one version, the principle of compositionality is a claim about our semantic competence, namely, that understanding the words in a sentence and the syntax of the sentence typically suffices for understanding the sentence. This is epistemic compositionality (e-compositionality). On another, more metaphysical, construal, the principle concerns language itself. It says that the meaning of a sentence typically supervenes on the meanings of the words in the sentence plus its syntax. We will call this ontic compositionality (o-compositionality). As noted above, systematicity is widely cited as a reason to believe in such principles. The connection between them, however, is more complex and attenuated than it may first appear. To start with, both e-compositionality and o-compositionality have to do mostly with semantics, and nothing else. As a result, considerations of g-systematicity, a broadly metalinguistic property, are of little significance. Instead, an argument to the best explanation from systematicity to compositionality will take one of two forms: either from p-systematicity to e-compositionality, or from r-systematicity to o-compositionality.

The line of argument from r-systematicity to o-compositionality is straightforward. We begin by assuming that a language *L* expresses the proposition *p*. This is equivalent to the claim that there is a sentence *s* in *L* that expresses *p*. According to

compositionality, the meaning of *s* is determined by the meanings of the words in *s* plus the syntax of the sentence. The same goes for structural variants of *s*, the meaning of which will be structural variants of *p*. If we suppose that *L* is compositional, then we get a ready explanation of the fact that *L* expresses a proposition *p* only if it expresses structural variants of *p*.

The line of argument from p-systematicity to e-compositionality is trickier. In order for the supposition that semantic competence is compositional to explain why that competence is systematic, it should follow from that supposition that the competence in question is systematic. But this is patently not the case. Assume that you understand a sentence *s*. The goal is to infer from this assumption that you understand structural variants of *s* as well. But the principle of e-compositionality says only that understanding the words and syntax of *s* suffices for understanding *s*; it does not say that understanding *s* suffices for understanding the words and syntax of *s*. Yet the latter assumption – the principle of reverse compositionality (Fodor and Lepore, 2001; Fodor, 2002) – is precisely what is needed in order to conclude, via the principle of compositionality, that understanding a sentence entails understanding its permutational variants. The amended argument is straightforward. If you understand *s*, then by reverse compositionality, you understand the syntax of *s* and the words occurring in *s*. These words can be re-ordered, *modulo* categorial constraints, within that syntactic structure to yield permutational variants of *s*. By compositionality, since you understand the words and syntactic structure of those variants, you also understand the variants. Hence, even if linguistic competence were compositional, that alone would not explain why it is systematic; one also needs to assume that it is reverse compositional.

A natural response to make at this juncture is that the phenomenon of p-systematicity warrants both e-compositionality and reverse e-compositionality. One problem with this move, however, is that the principle of reverse compositionality is probably false (Robbins, forthcoming). At a minimum, every theory of meaning on the market today, including the most austere versions of truth-conditional semantics, is incompatible with it (see **Meaning: Overview of Philosophical Theories**). For example, it’s possible to know the truth-conditions of the sentence *Pet fish have tails* without knowing that *pet* refers to pets and *fish* refers to fish. All one needs to know about the NP *pet fish* is that it refers to pet fish, and that fact is consistent with the assumption that *pet* refers to fish and *fish* refers to pets. Hence, if the truth-conditionalist story is correct, one can know the meaning of *Pet fish have tails* without knowing

the meanings of *pet* and *fish*. And non-truth-conditional accounts of meaning are in the same boat.

What's needed to escape this quandary, it seems, is a slight weakening of the thesis of minimal p-systematicity. Rather than saying that understanding a sentence strictly necessitates understanding some of its structural variants, we might say instead that instances of the first type of understanding are typically accompanied by instances of the second type. Such a pattern can be readily explained by the principle of compositionality together with a similarly watered-down form of reverse compositionality, according to which understanding a sentence is typically accompanied by an understanding of its syntax and the words contained therein. This in turn reveals how the systematicity of our semantic competence, however minimal in extent, militates in favor of its being compositional.

Tacit Knowledge

G S Rattan, University of Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

As Louise Antony and Norbert Hornstein (2003: 6) suggest, two of Chomsky's most significant philosophical contributions lie in his revival of mentalism in the philosophy of mind and rationalism in epistemology. Linguistics is the study of the system of knowledge possessed by speakers both innately (*see Innate Knowledge*) and in the relatively steady state condition of linguistic maturity. This knowledge is a kind of tacit knowledge. The aim of this article is to clarify some of the psychological and epistemic aspects of tacit knowledge, primarily as it is relevant to Chomskyan linguistics. As a psychological attitude, tacit knowing is distinguishable both from garden-variety kinds of propositional attitudes like believing and desiring (what I call full propositional attitudes) and from nonpropositional states or skills typically classified as instances of knowing how. The epistemic role of tacit knowledge in the broader issue of knowledge of meaning is discussed, and a more positive understanding of tacit knowing, with its distinctively epistemic gloss, is tentatively offered.

The Early Debate

It was clear to both Chomsky and his early critics that the kind of knowledge of language that speakers possess, if any, is not explicitly held. Speakers do not know explicitly the general principles to which human languages conform, or the grammars of the specific languages of which they are speakers. Chomsky and his early critics differed, however, on what they took to be the implications of that straightforward idea.

Critics argued that the invocation of psychological attitudes, especially knowing, was at best misleading and at worst wrong. The general objection is that the cognitive relation involved in the explanation of linguistic capacity, if indeed there is such a cognitive relation, cannot be that of knowing, because that cognitive relation does not sustain the connections

constitutive of knowledge (see, e.g., Stich, 1971: §4; Quine, 1972: 442; Devitt and Sterelny, 1999: 139; Dummett, 1991: 95–97). More specifically, early critics held that the states that underlie our ability to use language are, for most competent speakers, wholly unconscious, and when known, say by linguists, are known only indirectly through scientific theorizing. But, they contend, if one is to be ascribed a certain piece of knowledge, that knowledge should be recognizable 'from the inside' and not merely ascribable as a result of scientific theorizing. Let us say that having a full propositional attitude is constrained by a 'self-knowledge constraint,' according to which self-knowing is a distinctive, nontheoretical way of coming to know of one's attitudes and their contents.

Chomsky considers such objections (Chomsky, 1980, 1986) and replies as follows:

I have been speaking of "knowing English" as a mental state ... [But] to avoid terminological confusion, let me introduce a technical term devised for the purpose, namely "cognize," ... In fact I don't think that "cognize" is very far from "know" ... [Cognizing] is tacit or implicit knowledge, a concept that seems to me unobjectionable ... Cognizing has the structure and character of knowledge, but may be and in the interesting cases is inaccessible to consciousness. (Chomsky, 1980: 70–71)

The thrust of Chomsky's answer, then, is that if 'knowledge' offends, a technical term can be employed whose sense lacks precisely the offending features; but, continuing the response, the theoretical concept thereby introduced ought not to be thought of as fundamentally different from knowledge: it is knowledge, but it is unconscious, or not self-known.

Tacit Knowing vs. the Full Propositional Attitudes

We can see here an oversimplification of what might be involved in an account of the nature of propositional attitudes. There seems to be room to acknowledge both that speakers' knowledge of language does not sustain the connections constitutive of knowledge and the full propositional attitudes and

that, nevertheless, tacit knowledge is unobjectionable. The debate is oversimplified in turning only on a single, blunt constraint of self-knowledge. In what follows, I will try to enrich the debate by indicating considerations for thinking of tacit knowing as a propositional attitude without construing it as a full propositional attitude.

What more might be added to the understanding of the fully propositionally attitudinal to bring out its deep constitutive differences with tacit knowing? To begin with, we may take note of a pervasive feature of cognitive psychological theorizing, namely, that it construes the mind as modular: as segmented into mental components that use systems of encapsulated information that are inaccessible to conscious thinking, that are dedicated to representing highly structured or eccentric domains, and whose deployment is fast and mandatory (cf. Fodor, 1983). For the proponent of the idea that knowledge of language is a kind of tacit knowledge, the language faculty is itself, to a first approximation, such a modular system (Chomsky, 1986: chapter 1 [especially note 10]; Higginbotham, 1987; *see Cognitive Science and Philosophy of Language*).

The general properties of modular systems stand in sharp contrast with basic properties of the full propositional attitudes. The full propositional attitudes are inferentially integrated (Stich, 1978; Evans, 1981) and so can draw upon, and can be drawn upon, by a range of other full propositional attitudes (so they are neither encapsulated nor inaccessible) without regard to subject matter (so they are not dedicated). Although belief fixation may not be voluntary, it seems not to be mandatory in the sense in which the operation of modular systems is. The latter is a compulsion by psychological law; the former is something like a compulsion by reason (more on this below). Finally, the operation of the full propositional attitudes can be painfully slow. Reasoning can take a long time. These differences show that, on its own, the self-knowledge constraint is quite incomplete as to what is distinctive about the way that the information contained in the language faculty is held.

The point about modularity concerns primarily the nature of the attitude of tacitly knowing. But consider as well what Gareth Evans (1982) has called the 'generality constraint,' which pertains to the objects of the full propositional attitudes, thoughts or propositions, and their constituents, concepts (*see Concepts*). According to the generality constraint, concepts possess an inherent generality that mandates their recombining with appropriate concepts of other logical categories; slightly more formally, thoughts are closed under logico-syntactic formation

rules, up to conceptual incoherence or anomaly (cf. Peacocke, 1992: 42).

Now, no explanatory point seems to be served by imposing such a constraint on the representation of the information deployed in the language faculty. Speakers tacitly know the grammar that they do; knowledge of that grammar is deployed in some way or other, through the actions of mechanisms implementing algorithms that deploy the grammatical information tacitly known, so as to allow the acquisition, production, and perception of linguistic forms. Insisting that the constituents of the representation of linguistic information be subject to the generality constraint in no way illuminates the explanatory role of tacit knowing.

The reason can be clarified by thinking about the basic theoretical aims and motivations for both the full propositional attitudes and their contents. The full propositional attitudes and their contents are the fundamental theoretical entities in the conceptualization and explanation of the epistemic and practical successes and failures of agents. The explanations trace and assess the complexes of reasons for which agents believe and act, and implicitly evaluate those complexes, and agents, against an ideal of rational epistemic and practical functioning. The notions of epistemic and practical responsibility get their grip here, in the gap between actual and ideal. Since rational inference requires the interactions of attitudes and the recombination of concepts in a variety of ways, attitudes and contents must be such as to sustain the actual evaluations of epistemic status of agents in their inferential practices (Rattan, 2002: §4). The requirements that the full propositional attitudes be inferentially integrated and that concepts obey the generality constraint reflect these normative dimensions of the roles of attitudes and contents.

These ideas suggest, then, a deep point of contact with the self-knowledge constraint: that constraint will be relevant, like inferential integration and generality, insofar as it reflects fundamental features of rational practice. And surely it does. Reflecting on one's attitudes is a way of increasing the rational status of those attitudes. But if reflection plays that rational role, then it must be that our access to our attitudes is reliable and possessed of entitlement (cf. Burge, 1996); our access to our own minds must in the most basic cases be knowledge. Demanding that the attitudes and their contents be self-known, then, is part of a general account of the full propositional attitudes and their contents that construes them so that they may play their role in conceptualizing and explaining the normative statuses of agents.

Tacit Knowing vs. Knowing How

But it may be objected that for all that has been said so far, tacit knowing may not be a kind of content-bearing state at all; given the deep differences between tacit knowing and the full propositional attitudes, tacit knowing simply seems not to be a genuine mental attitude toward contents.

The objection can be elaborated by insisting that speaking a language is not a matter of knowing propositions at all. As Michael Devitt and Kim Sterelny put it:

[C]ompetence in a language does not consist in the speaker's semantic propositional knowledge of or representation of rules. It is a set of skills or abilities ... It consists in the speaker being able to do things with a language, not in his having thoughts about it. (Devitt and Sterelny, 1999: 187)

Perhaps there are no states of knowing the facts about the language – no knowing the rules or grammar of the language. A speaker no more knows the rules of the grammar than one who can ride a bike knows the laws of mechanics governing balance and maneuver. The language faculty is a faculty of knowing how to speak a language. Call the proponent of such a view the 'knowing-how theorist.'

Of course it cannot be denied that speakers do know how to speak the language; but the knowing-how theorist must justify the idea that attributions of knowing **how** are not just species of attributions of knowing **that**, as certain syntactic and semantic evidence suggests (Stanley and Williamson, 2001). Again, it looks as though the knowing-how theorist simply misses the point: although speakers know how to speak the language, that is not an explanation, but a description of what needs to be explained (cf. Higginbotham, 1994). But let us suppose that the knowing-how theorist is proposing an alternative explanation, one that does not appeal to tacit knowing. The knowing-how theorist has at least two significant hurdles to overcome.

First, suppose it is granted that tacit knowing does not have the direct role in rationalizing conceptualizations and explanations that the full propositional attitudes do. There still seems to be nothing to prevent thinking of tacit knowings as having the same attitude-content structure that the full propositional attitudes do. The attitude is not, admittedly, understood as playing a certain rational role, but it still may have a regular and lawlike causal role, and that would seem to be enough to think of there being something attitude-like – a distinctive way in which the information is held – in the picture. (Indeed this is the usual

understanding of the attitudes in causal functionalism; see, for example, Lewis, 1972.) This, for example, is what we might like to say about animals and their attitudes. They fail to have states that satisfy the normative constraints that the full propositional attitudes do, but it would be theoretically heavy handed to say that they do not have states that are very much belief- and desire-like.

Again, serving the aims of rationalizing explanations may require that contents be individuated at the level of Fregean sense rather than reference; this is the point of 'Frege's Puzzle' (Frege, 1892). But if tacit knowings fail to figure directly in these kinds of rational phenomena, then their contents may legitimately be exempted from having the general properties that the contents of attitudes that do so figure must have. The contents of tacit knowings may be Russellian, or have a limited need for cognitive difference without difference in reference (see **Sense and Reference: Philosophical Aspects**). These constituents of contents, objects and properties, presumably do not obey the generality constraint, so there are ways in which contents may be involved yet fail to be like the contents of the full propositional attitudes. The issues here are complex, and I mean only to flag the general issue about the individuation of the contents of tacit knowings and how that may serve to distinguish them from the contents of the full propositional attitudes.

Second, perhaps the proponent of knowing how thinks that the explanation of linguistic ability is merely dispositional, like the explanation of the shattering of a glass by appeal to its fragility. Here, there is some categorical, microstructural, property of the glass that, simplifying tremendously, explains why in conditions of the appropriate sort, the glass shatters. In a like manner the knowing-how theorist may appeal to the categorical neurophysiological ground of linguistic dispositions as comprising a nonintentional explanatory level. This idea, however, is subject to all the general objections that favor functional explanations over neurophysiological ones. It neglects a tradition of thinking about psychological explanations as involving multiple – computational, informational, algorithmic, and implementational – levels (see Marr, 1982; Peacocke, 1986). Indeed the functional states will be realized by neurophysiological states, but the explanation will be cashed out at some level that abstracts from neurophysiological description.

What Is Tacit Knowledge?

So far tacit knowing has been negatively characterized, by being distinguished from both the full

propositional attitudes and knowing how. But how are we to understand the nature of tacit knowledge in more positive terms? Tacit knowing plays a role in the explanations of linguistic acquisition, perception, and production. The described capacities are epistemic in character. Their explanations are part of more elaborate explanations that seek to understand the general phenomenon of communication, including its substantial pragmatic elements. To keep the discussion manageable, I will ignore the more elaborate problems. As well, I will focus only on the problems of linguistic perception and linguistic production. I mean only to gesture roughly at the kinds of considerations that are involved.

According to these explanations, speakers are able to make knowledgeable sound-meaning pairings for sentences because they have information about the phonological, syntactic, and semantic – grammatical – properties of the expression-types that make up those sentences. This information is drawn on by perceptual and production mechanisms. Simplifying immensely, production mechanisms take inputs from intentions to say that *p*, and make available to a speaker, through the use of the grammatical information, expression types that mean that *p*. Perceptual mechanisms take acoustic inputs and, through the use of grammatical information, impose grammatical properties on them, eventuating in an experience of meaning, on the basis of which meaning judgments are made (cf. Fricker, 2003). A fully fleshed out epistemology of meaning would explain the epistemic differences between knowing one's own meaning in production and knowing others' meanings in perception by, for example, considering how the inputs to production and perception, respectively, allow for different kinds of mistakes in the eventuating judgments about meaning.

Let us assume that information is deployed in speakers' linguistic epistemic achievements (so these achievements are not examples of knowing how), and that this information is tacitly rather than explicitly held (so it is not an example of a full propositional attitude). Still, why must we accept that this information is known rather than just truly believed? The question is difficult and fundamental. I offer here some potential lines for understanding.

Suppose, as I have been suggesting, that tacitly held information or content is involved in the explanation of linguistic capacities. Two things are of note here about this information. First, these representations have been formed by a reliable mechanism – one that uses speakers' innate representations of Universal Grammar – that reproduces the grammatical information represented in the minds of speakers in one's community. In normal environments, acquiring

these representations will equip one to come to judge knowledgeably the meanings of other speakers. Second, once one moves away from folk conceptions of public language, it is plausible to think of the facts about which language one speaks as settled by one's grammatical representations or I-language (Chomsky, 1986: Chapter 2; Higginbotham, 1991; Barber, 2001; *see E-Language versus I-Language*). Judgments about what one means oneself will then be reliably produced, again as outlined above; and since the facts about one's language are determined by one's grammatical representations, they will be reliably produced by the facts that determine the language one speaks. It seems that as a phenomenon at the level of the full propositional attitudes, knowing our own meanings and knowing the meanings of others, when we do, is not an accident.

We can think of the foregoing as giving the outlines of a philosophical explanation of what might be called the success-presupposing features of the explanation of our linguistic capacities. The explanations are not success neutral (see Burge, 1986, who attributes the phrase to Bernard Kobes), in that the explanations are explanations of epistemic capacities that are generally presumed to be successful. But if that is right, we are in a position to say something about why the information tacitly held is knowledge. Unless that information were known, rather than just truly believed, it would seem to be a mystery why drawing on that information in perception and production leads in general to knowledge. So one suggestion is that the status of the information as knowledge comes from the distinctive explanatory role of the tacitly held information in explanations of our generally epistemically successful linguistic capacity.

That's one pass at vindicating the attribution of knowledge. But perhaps something deeper can be said. Here we can return to Chomsky's rationalism. Sometimes Chomsky's rationalism seems to be a genetic rationalism that emphasizes the innate character of Universal Grammar, vindicating an early modern doctrine of innate ideas (*see Innate Ideas*). But there is another way to think of this rationalism, in which it emerges as a more full-blooded epistemic doctrine. In this way of thinking, at some point in the evolution of humankind, minds came into a cognitive relation with certain abstract structures, with very valuable combinatorial properties. These abstract structures are languages. We have already seen that the tacit is not the realm of epistemic and practical responsibility. So the status of knowledge for tacit representations will not accrue as a result of some personal-level achievement. The status of knowledge for the representations that underlie our linguistic capacity derives instead from a

natural attunement of the modular structures of the human mind to the abstract combinatorial structures of language.

Tense Logic

Tense Logic was introduced by Arthur Prior (1957, 1967) as an aid to elucidating various philosophical problems concerning time. Because it was used to provide formal renderings of propositions originally formulated as natural language sentences, it was natural to consider Tense Logic also as a tool for linguistic analysis in the context of linguistics rather than philosophy. As such, it was soon found to have considerable limitations, which stimulated the

development of extensions or alternatives to Tense Logic as it had been conceived originally by Prior.

Syntax of Priorean Tense Logic

Prior took the basic expressions of temporality in ordinary language to be the past, present, and future tenses. For the past and the future, he introduced proposition-forming operators *P* and *F*, called **tense operators**, which, when prefixed to any proposition ϕ , yielded propositions that expressed, respectively, the past-tense and future-tense versions of ϕ , for example:

- ϕ : It is raining.
- $P\phi$: It was raining.
- $F\phi$: It will be raining.

(More often, in fact, Prior would render $P\phi$ in the form ‘It has been raining’, using the present perfect rather than the simple past. In English, this reads more naturally because ‘It was raining’ seems to refer implicitly to some particular time assumed known.)

Used in combination with the standard connectives of Propositional Logic ($\wedge, \vee, \rightarrow, \leftrightarrow, \neg$), Prior’s tense operators allowed one to express temporal relationships, e.g., using ϕ for ‘John arrives’ and ψ for ‘Mary leaves’,

- $P(\phi \wedge \psi)$: John arrived when Mary left.
- $P(\phi \wedge P\psi)$: When John arrived, Mary had left.
- $F(\phi \wedge P\psi)$: When John arrives, Mary will have left.

This kind of analysis is too crude to capture the nuances of expression possible in natural language. Whereas the formulae $P(\phi \wedge \psi)$ and $P(\psi \wedge \phi)$ are logically equivalent, the sentences ‘John arrived when Mary left’ and ‘Mary left when John arrived’ are not. It might be argued, however, that the two sentences share some ‘core’ semantic content, and that this is what is expressed by the logical formulae. On this basis, Tense Logic is worth studying for the clarity it affords in analyzing at least some aspects of the linguistic expression of time.

Of particular interest is the interaction of the tense operators with negation. The formula $\neg P\phi$ says it has never been true that ϕ ; it is not equivalent to $P\neg\phi$, which merely says it has (at least once) been false that ϕ . Reading ϕ as ‘The prime minister of the UK is a woman’, $\neg P\phi$ is false (because of Margaret Thatcher), whereas $P\neg\phi$ is true (because of all the other prime ministers). The negation of the latter, $\neg P\neg\phi$, says it has never been false that ϕ , and hence that ϕ has always been true. Prior introduced a new operator, H , as an abbreviation for the sequence $\neg P\neg$, and analogously G for $\neg F\neg$. The full set of operators is now

- $P\phi$: It has been the case that ϕ (on at least one occasion).
- $H\phi$: It has always been the case that ϕ .
- $F\phi$: It will be the case that ϕ (on at least one occasion).
- $G\phi$: It will always be the case that ϕ .

Using these, Prior could enunciate tense-logical theses such as $\phi \rightarrow GP\phi$, which says that if ϕ is true now then it will always be the case that ϕ has been true.

Semantics of Tense Logic

To express the meaning of the tense operators, we assume that propositions are evaluated as true and false at times, that a proposition may be true at some

times and false at others, and that times are ordered by the relations *earlier than* and *later than*:

- $P\phi$ is true at time t if and only if ϕ is true at some time t' earlier than t .
- $H\phi$ is true at time t if and only if ϕ is true at every time t' earlier than t .
- $F\phi$ is true at time t if and only if ϕ is true at some time t' later than t .
- $G\phi$ is true at time t if and only if ϕ is true at every time t' later than t .

In the standard formal semantics for Tense Logic, a temporal frame is a pair $(T, <)$, where T is a set of times, and $<$ is a binary relation on T . For $t, t' \in T$, we understand $t < t'$ as the formal counterpart of the relation ‘ t is earlier than t' ’. An interpretation \mathcal{I} over frame $\mathcal{F} = (T, <)$ assigns a truth value to each atomic formula at each time in the frame. The fundamental semantic relation is satisfaction of formula ϕ at time t in frame \mathcal{F} under interpretation \mathcal{I} , symbolized as $\mathcal{F}, t \models_{\mathcal{I}} \phi$. If this does not hold, we write $\mathcal{F}, t \not\models_{\mathcal{I}} \phi$. We assume that all such relations are known for each *atomic* formula at each time; the truth values of compound formulae are determined by the semantic rules:

- $\mathcal{F}, t \models_{\mathcal{I}} P\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for some $t' \in T$ such that $t' < t$.
- $\mathcal{F}, t \models_{\mathcal{I}} H\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for every $t' \in T$ such that $t' < t$.
- $\mathcal{F}, t \models_{\mathcal{I}} F\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for some $t' \in T$ such that $t < t'$.
- $\mathcal{F}, t \models_{\mathcal{I}} G\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for every $t' \in T$ such that $t < t'$.

(For Boolean compounds with \wedge, \vee , etc., the standard rules are used.)

Some tense-logical formulae can now be proved to be universally valid, i.e., satisfied at every time in every frame. An example is Prior’s formula $\phi \rightarrow GP\phi$. For suppose $\mathcal{F}, t \models_{\mathcal{I}} \phi$, and let $t' \in T$ be any time such that $t < t'$. Then the semantic rule for P implies $\mathcal{F}, t' \models_{\mathcal{I}} P\phi$. Because this holds for every $t' \in T$ such that $t < t'$, the rule for G gives us $\mathcal{F}, t \models_{\mathcal{I}} GP\phi$, as required. The formulae provable in this way constitute a system known as Minimal Tense Logic, generally designated K_t .

Because the class of all temporal frames imposes no constraints on the nature of the $<$ relation, K_t does not provide an adequate basis for reasoning about temporal relationships. It is therefore usual to restrict the class of frames by requiring $<$ to satisfy certain structural properties such as transitivity, density, or linearity. A transitive frame $(T, <)$, for example, obeys the rule

$$\text{TRANS } \forall t, t', t'' \in T (t < t' \wedge t' < t'' \rightarrow t < t'')$$

i.e., if t is earlier than t' , which in turn is earlier than t'' , then t must be earlier than t'' . It can be shown that TRANS characterizes transitive frames in the following sense:

The frame $\mathcal{F} = (T, \prec)$ is transitive if and only if
 $\mathcal{F}, t \models_{\mathcal{I}} \text{TRANS}$ for every interpretation \mathcal{I} over \mathcal{F} ,
 and every time $t \in T$.

Much attention has been given to the problem of finding tense-logical formulae which correspond to first-order frame properties just as TRANS corresponds to transitivity (Van Benthem, 1991). Not all frame properties have corresponding tense-logical formulae, and conversely, not all tense-logical formulae correspond to first-order frame properties. Thus, there is no first-order characterization of the frames for which $GF\phi \rightarrow FG\phi$ holds; and no tense-logical formula exactly characterizes the *irreflexive* frames, which satisfy $\forall t \neg(t \prec t)$.

Extensions of Tense Logic

Increasing the Expressive Power: 'Since' and 'Until'

Sentences such as *John has been happy since Mary arrived* and *John will be happy until Mary arrives* cannot be expressed using Prior's operators. In 1968, Hans Kamp introduced binary operators S and U with the following semantics:

$\mathcal{F}, t \models_{\mathcal{I}} S\phi\psi$ if and only if there is a time
 $t' \prec t$ such that
 (i) $\mathcal{F}, t' \models \phi$, and
 (ii) $\mathcal{F}, t'' \models \psi$ for every $t'' \in T$ such that $t' \prec t'' \prec t$.
 $\mathcal{F}, t \models_{\mathcal{I}} U\phi\psi$ if and only if there is a time
 $t' \prec t$ such that
 (i) $\mathcal{F}, t' \models \phi$, and
 (ii) $\mathcal{F}, t'' \models \psi$ for every $t'' \in T$ such that $t \prec t'' \prec t'$.

Let ϕ stand for 'Mary arrives' and ψ for 'John is happy'. Then $S\phi\psi$ is true now so long as Mary arrived at some past time, and John was happy at every time between then and now – in other words, John has been happy since Mary arrived. Similarly, $U\phi\psi$ is true now if Mary will arrive at some future time, and John will be happy at every time between now and then. This implies John will be happy until Mary arrives, but is not equivalent to it, because the English sentence would also be true if Mary never arrives, so long as John remains happy forever. This can be expressed as $U\phi\psi \vee G\psi$.

Kamp showed that for frames in which the flow of time is ordered like either real numbers or integers, the operators S and U suffice to express every first-order property expressible by means of \prec and quantification over times. In this sense, the logic of S and

U is *expressively complete* in a way that the logic of P , F , G , and H is not.

The Indeterminate Future

Although it is natural to suppose that a temporal frame should be linear, the need has frequently been felt for temporal frames with a branching structure. In a linear frame, given two distinct times, one must precede the other: $\forall t, t' \in T (t = t' \vee t \prec t' \vee t' \prec t)$. The most popular form of non-linear structure is a *future-branching* frame, in which each time has a unique linear past, but may have many distinct futures. This is secured by the 'left-linearity' axiom that restricts linearity to times in the past of a given time: $\forall t, t', t'' (t \prec t'' \wedge t' \prec t'' \rightarrow t = t' \vee t \prec t' \vee t' \prec t)$.

This kind of structure supports reasoning about alternative *possible futures*: it captures the idea that whereas the past is fixed, the future is indeterminate. This means that some future events are inevitable (occurring in every possible future) whereas others are merely possible (occurring in some but not all possible futures). To quantify possible futures, we introduce modal operators. One way of doing this is as follows: $\Diamond\phi$ says there is a possible future which makes ϕ true now (so ϕ is possible), while $\Box\phi$ says that every possible future makes ϕ true now (so ϕ is necessary). The semantics makes explicit reference to possible futures; a *history* is any maximal linear subset of T , and formulae are evaluated with respect to pairs (H, t) , where H is a history and $t \in H$. Semantic rules for the existing operators can be straightforwardly rewritten by incorporating a single history term, as e.g.,

$\mathcal{F}, H, t \models_{\mathcal{I}} F\phi$ if and only if $\mathcal{F}, H, t' \models_{\mathcal{I}} \phi$ for some
 $t' \in H$ such that $t \prec t'$.

For the new modal operators, we have the rules

$\mathcal{F}, H, t \models_{\mathcal{I}} \Diamond\phi$ if and only if $\mathcal{F}, H', t \models_{\mathcal{I}} \phi$ for
 some history H' such that $t \in H'$
 $\mathcal{F}, H, t \models_{\mathcal{I}} \Box\phi$ if and only if $\mathcal{F}, H', t \models_{\mathcal{I}} \phi$ for
 every history H' such that $t \in H'$

In these rules, because t is in both H and H' , and branching is only into the future, these histories must coincide at least up to t . We can now interpret compound formulae such as

$\Diamond F\phi$ ϕ will be true in some possible future.
 $\Box F\phi$ ϕ will be true in every possible future.
 $P\Box\phi$ It was inevitable that ϕ would eventually be true.

Interval Semantics

In the standard semantics for Tense Logic, the elements of a temporal frame are instants, that is,

temporal elements lacking duration. A further possibility is to use temporal frames containing intervals as well as, or instead of, instants. This approach has been favored by those seeking to give a logical account of aspect in natural language, which requires us to handle events that take time (Dowty, 1979). The statement *John runs a mile* ($=\phi$) reports the occurrence of an event of several minutes' duration. It seems inappropriate to evaluate ϕ at instants, because there is no instant at which John runs a mile. Instead, interval semantics evaluates ϕ as true with respect to any interval i over which John runs a mile. Because running a mile is an accomplishment (Vendler, 1967), this means that ϕ will not be true on any proper subinterval of i —in contrast to the progressive form *John is running a mile*, which would be true.

Formally, we use frames of form $\mathcal{F} = (I, \prec, \sqsubset)$, where I is a set of intervals, \prec is the 'earlier than' relation on intervals, and \sqsubset is the proper subinterval relation. Accomplishments and activities are distinguished by their different entailments: an accomplishment sentence satisfies the rule

(ACC) If $\mathcal{F}, i \models_{\mathcal{I}} \phi$ and $i' \sqsubset i$ then $\mathcal{F}, i' \not\models_{\mathcal{I}} \phi$,

whereas an activity sentence satisfies

(ACT) If $\mathcal{F}, i \models_{\mathcal{I}} \phi$ and $i' \sqsubset i$ then $\mathcal{F}, i' \models_{\mathcal{I}} \phi$.

The progressive aspect might be regarded as an operator *Prog* for (among other things) converting accomplishments into activities. The following semantic rule for *Prog* is plausible:

$\mathcal{F}, i \models_{\mathcal{I}} \text{Prog}(\phi)$ if and only if $\mathcal{F}, i' \models_{\mathcal{I}} \phi$ for some i' such that $i \sqsubseteq i'$,

and this rule has the consequence that if ϕ is an accomplishment (as defined by ACC) then *Prog*(ϕ) is indeed an activity (as defined by ACT). Thus, basic Tense Logic can be enhanced to capture some of the complexities of temporality in natural language.

This analysis only covers cases where *Prog*(ϕ) is true by virtue of an eventually completed occurrence of the event expressed by ϕ . By the so-called 'imperfective paradox', the former can be true without the latter ever becoming true (e.g., if John stops running before the mile is completed). This property can be captured by combining interval semantics with branching time. A history is now a maximal linear set of intervals (where linearity of a set of intervals can be defined in terms of \prec and \sqsubset). A more accurate rendition of the progressive is now

$\mathcal{F}, H, i \models_{\mathcal{I}} \text{Prog}(\phi)$ if and only if $\mathcal{F}, H', i' \models_{\mathcal{I}} \phi$ for some H, i' such that $i \sqsubseteq i' \in H'$.

Because i is in both H and H' , and branching is only into the future, H and H' must coincide at least up to

the end of i ; thereafter they may – but need not – diverge, allowing for the possibility that the completion of ϕ occurs in a different history from the one in which *Prog*(ϕ) is being evaluated.

Other Forms of Temporal Logic

The systems discussed above may be thought of as variants of Prior's basic Tense Logic, expressing temporal properties and relations by means of operators. Alongside these, there has been a tradition of modeling temporal information in first-order logic, using individual terms as explicit bearers of temporal reference. Whereas classically one might write, say, *Asleep(john)* for *John is asleep*, the *Method of Temporal Arguments* writes *Asleep(john, t)* to say that John is asleep at time t . Tenses are paraphrased using constructions that mirror the semantic rules for tense operators, e.g., $\exists t' (t' \prec t \wedge \text{Asleep}(\text{john}, t'))$ says that 'John has been asleep' holds at t . For events that take time, we use interval arguments, e.g., *Run(john, mile, i)*, where s is the interval over which John runs a mile.

A well-known variant of this method, from Donald Davidson (1967), replaces temporal arguments by terms denoting individual events, e.g., $\exists e (\text{Run}(\text{john}, \text{mile}, e) \wedge t' \text{Occurs}(e, i))$, which says that some event e is the running of a mile by John and occurs on interval i . An advantage of this is that it allows us to analyze adverbial modifiers by means of additional event predicates linked by logical conjunction, e.g., $\exists e (\text{Run}(\text{john}, \text{mile}, e) \wedge \text{Occurs}(e, i) \wedge \text{In}(e, \text{field}))$.

Davidson's method is sometimes known as 'event-token reification', because the e terms refer to *event tokens*, i.e., individual occurrences. An alternative form of reification, particularly favored in Artificial Intelligence, involves state and event *types* (Allen, 1984). In this method, *run(john, mile)* is a *term* denoting the event type 'John runs a mile'; an occurrence of this type on interval i is expressed as *Occurs(run(john, mile), i)*. A separate predicate is used for state-types, e.g., *Holds(asleep(john), i)*, meaning that John is asleep *throughout* interval i . An advantage claimed for this style of analysis is that by allowing quantification over types it enables expression of general temporal knowledge concerning, for example, causality, e.g., $\forall e, s, e', d (\text{Cause}(e, s, e', d) \wedge \text{Holds}(s, t) \wedge \text{Occurs}(e, t) \rightarrow \text{Occurs}(e', t + d))$. The first conjunct states that events of type e occurring under condition s give rise to events of type e' after a delay of length d .

Tense and Time: Philosophical Aspects

L N Oaklander, University of Michigan–Flint, Flint, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

As we ordinarily think and talk about time, it is a truism that time passes. Dates, like the events that occur at those dates, are once in the future, then become present, and then recede into the more and more distant past with the passage of time. To think of time as passing, and events as changing with respect to the characteristics of pastness, presentness, and futurity, is to conceive of the transient aspect of time or temporal becoming. The most fundamental debate in the philosophy of time concerns the status of temporal becoming. Do events **really** pass from the future to the present and into the past, as tensed- or A-theorists (derived from McTaggart's 1908, 1927 A-series of past, present, and future moments or events) such as C. D. Broad (1923, 1938), Richard Gale (1968), A. N. Prior (1967), George Schlesinger (1980), Quentin Smith (1993), Storrs McCall (1994), Michael Tooley (1997), William Lane Craig (2000a, 2000b), and others have maintained? Or is the passage of time a myth and an illusion, as B-theorists (derived from McTaggart's B-series of events ordered by the relations earlier, later, and simultaneous) such as Bertrand Russell (1915), J. J. C. Smart (1980), Robin Le Poidevin (1991), D. H. Mellor (1998), L. Nathan Oaklander (2004b) and others have maintained? That is one issue. Another closely connected issue concerns the proper analysis of tense in ordinary language and thought. We express the passage of time (or the myth of passage) by means of tensed discourse and tensed beliefs. For example, we ordinarily say, at different times, that an event will occur, is occurring,

and did occur, and it is commonplace to believe that, for example, today is Monday, tomorrow will be Tuesday, and yesterday was Sunday. Two questions of analysis concerning these ordinary tensed sentences and beliefs immediately arise: (1) What is the meaning of tensed discourse? and (2) what are the truth conditions or truthmakers of tensed sentences? A third issue, intimately related to the other two, concerns the reference of temporal indexicals (such as now, 'yesterday,' and 'tomorrow'). Do temporal indexicals refer directly to some items (such as times or sentence tokens); or do they refer indirectly to items via a mediating sense (such as the property of **presentness**); or do they, perhaps, perform both functions, or neither?

Although these issues are fundamentally metaphysical in nature, the dispute between the A- and B-theorists has, until the 1980s, centered on temporal language. Defenders of the B-view have often argued that since tensed discourse could be eliminated or translated without loss of meaning into tenseless discourse, an adequate account of the nature of time need not countenance any special kind of tensed fact or tensed properties. In other words, the old B-theory of time assumed that a logical analysis of ordinary language that eliminates tensed discourse supported an ontological analysis of time that rejects transient temporal properties of **pastness**, **presentness**, and **future**, or any other form of passage. The A-theorist shared that assumption, but argued that since no tenseless translations were successful, temporal becoming in some form or another is necessary in any adequate account of time. A-theorists claim, in other words, that because tensed discourse is ineliminable, the B-theorist is mistaken and tensed properties and facts must exist.

For a variety of reasons, some having to do with arguments in the philosophy of time and some having to do with arguments in the philosophy of language, recent defenders of the B-theory have come to embrace the thesis that tensed sentences cannot be translated by tenseless ones without loss of meaning. The reason for this is clear. It is part of the meaning of sentences reflecting temporal becoming that they change their truth value with the passage of time. For example, a token (or instance) of the sentence type 'I will be celebrating my 60th birthday in the future' is true today, on January 7, 2005, but in six months another token of that sentence will be false. On the other hand, it is part of the meaning of tenseless sentences expressing temporal relations between events that different tokens of the same tenseless sentence have the same truth value whenever they are expressed. Thus, for example, the linguistic meaning of the sentence (S) 'My 60th birthday is future' cannot be captured by (V) 'My 60th birthday is later than January 7, 2005' even if (S) is uttered on January 7, 2005, since (V) is always true, whereas on July 7, 2005 (S) is not.

Nevertheless, recent B-theorists have denied that the ineliminability of tensed language and thought entails the reality of temporal properties or temporal becoming. According to the new B-theory of time, our need to think and talk in tensed terms is perfectly consistent with its being the case that time itself is tenseless. Tensed discourse is indeed necessary for timely action, but tensed facts are not, since the truth conditions of tensed sentences can be expressed in a tenseless metalanguage that describes unchanging temporal relations between and among events.

There are two popular versions of the new B-theory of time, the token-reflexive account (Mellor, 1981) and the date-analysis account (Smart, 1980). On the token-reflexive account the temporal relation between the date at which one says, thinks, or writes down a tensed sentence and the event or thing that it is about provides an objective basis for the truth-value of any tensed sentence. A present-tense sentence token is true if, and only if, it occurs (exists tenselessly) at (roughly) the same time as the event it is about; a past-tense token is true if, and only if, it occurs at a time later than the event it refers to, and so on. Thus, on the token-reflexive account the truth conditions of tensed sentence and judgment tokens are tenseless facts – that is, facts that involve only temporal relations between and among nontensed events.

The date-analysis version of the new B-theory also denies the thesis of linguistic reducibility and claims instead that corresponding to every tensed sentence-token is a tenseless sentence that gives its truth conditions. For example, J. J. C. Smart (1980) claims that

the notion of becoming present seems a pretty empty notion, and this is even more obvious when we recognize the indexical nature of words like 'present', 'past' and 'future'. When a person P utters at a time *t* the sentence 'Event E is present' his assertion is true if, and only if, E is at *t*. More trivially, when P says at *t* 'time *t* is now' his assertion is true if, and only if, *t* is at *t* so that if P says at *t* 't is now' his assertion is thereby true" (1980: 11).

The heart of the date-analysis thesis is that temporal indexicals like 'now,' 'this time,' and 'the present,' as used on a given occasion, are referring terms that denote a time. Thus, if a temporal indexical sentence such as 'Event E is now occurring' is uttered at *t*₁, then it reports an event that is identical with the event reported at any time by the use of the nonindexical sentence 'Event E is occurring at *t*₁.' On this view, indexicals and proper names such as dates are rigid designators (Kripke, 1980). Thus, a tensed sentence like 'It is now 1980,' uttered in 1980, reports the same fact as the necessary truth reported by 'It is 1980 in 1980' or '1980 is at 1980.' It does not follow, nor is it part of the date-analysis thesis to maintain, that 'It is now 1980' and '1980 is at 1980' express the same proposition or have the same meaning (Beer, 1988). Nevertheless, to know that the truth condition of a tensed sentence token is a function of the date of its occurrence, and what it is about, is to know the meaning of a tensed sentence (Mellor, 1998).

Both versions of the new B-theory have been the subject of considerable debate. Proponents of the A-theory have argued that the B-theory cannot give an adequate account of the truth conditions of A-sentences, whereas B-theorists have denied this (see Oaklander and Smith, 1994, Part I; Le Poidevin, 1998; Smith, 1999; Craig, 2000b; Mozerky, 2000; and Dyke, 2002, 2003a). More recently, Oaklander (2004a) has argued that tensed sentence-tokens and the mind-independent contents they express, while pragmatically useful and perhaps indispensable, are strictly and metaphysically false and couldn't possibly be true since McTaggart's paradox (to be considered shortly) has demonstrated that the A-theory of time is contradictory.

In summary, the issue that now rages between the various camps in the A/B-theory debate concerns the truth conditions of statements that reflect temporal becoming and temporal relations. In this context, truth conditions are truthmakers: the basis in reality for those true sentences that record facts about the transitory and temporal relational aspects of time. Thus, the A/B debate centers on the questions: What, if anything, do the tenses and our use of temporal concepts reflect about the metaphysical nature of time? And, What is the ultimate metaphysical foundation of our experience of succession and

temporal relations? To deal with these questions it is necessary to consider McTaggart's paradox.

McTaggart maintained that becoming is an essential feature of temporal reality, since without real passage there is no change, and without change there is no (B-) time. If events simply stand in the unchanging relations of earlier/later than, nothing would first have a property and then lose it. Thus, in order for there to be change, it must be the case that events have the properties of pastness, presentness, and futurity and change with respect to those determinations. McTaggart argued, however, that such change was impossible. For if every event is past, present, and future, then since A-characteristics are incompatible, we arrive at a contradiction. Of course, the seemingly obvious way out of the 'paradox' is to appeal to tense: it is not the case that every event is (simultaneously or tenselessly) past, present, and future, but rather every event either is past, was future and present; or is present, will be past, and was future; or is future and will be past and present. This way of avoiding the paradox is well taken, but it certainly is not the last word, since we need to understand how the tenses 'is now,' 'was,' and 'will be' are to be interpreted if we are to understand how such an account is to render temporal becoming possible.

A currently fashionable A-view of the tenses is called 'presentism.' According to this view, only the present exists; the past and future are species of unreality, that is, the past and future tenses are operators (with no ontological significance) on present tense sentences (Prior, 1967; Hinchliff, 1996). Given that only the present exists, there is no longer any problem of how one and the same event (or moment) can have incompatible A-determinations, since there is only one A-characteristic, namely presentness.

Nevertheless, presentism is not without its difficulties. To see why, suppose we start with

FPe & Ne & PFe

This is read as 'e will be past' and 'e is present' and 'e was future.' Perhaps there is no contradiction in such a representation of becoming, but we are still left with the question: What are the truthmakers for the first and last conjuncts? More specifically, what is the ontological difference between *FPe* and *PFe*, given that neither 'F' nor 'P' is a predicate that ascribes properties to *e*? Without such an account, the appeal to grammatically consistent tensed statements is a vacuous response to McTaggart's paradox.

The B-theory, in rejecting temporal passage as an objective feature of reality over and above the tenseless existence of events spread along the four-dimensional manifold, avoids McTaggart's conundrum, but it has questions of its own to answer.

If events don't really pass, then why do we talk as if they do? And if nothing is really present, then what account can be given on the presence of experience, and our experience of the present? (For a discussion of proposed solutions to these questions see Oaklander and Smith, 1994, Part III; Dyke and Maclaurin, 2003; and Oaklander, 2004b, Part III).

Testimony

Testimony as a Belief Source

A belief source is a cognitive process that takes certain characteristic mental states as input and yields the representational state of belief as output. In the broadest sense of interest to epistemologists, testimony may be understood as a belief source whose input and output consist, respectively, of (a) reception of another's report about the world and (b) belief in what is reported. As such, testimony has a wide variety of manifestations, ranging from the highly formal to the exceedingly mundane – from taking the word of a sworn witness in a legal trial to accepting the nutritional information on a box of cereal.

Reflection on the ubiquity of testimony in this broad sense highlights the importance of language for our representation of the world. Thus, compare testimony with such belief sources as sensory perception, inference, and retentive (as opposed to recollective) memory, which may be characterized roughly as in the first three rows of **Table 1**.

In the case of the nontestimonial belief sources, description of the salient input need not explicitly mention language. Regarding testimony as a belief source, however, the appeal to language is unavoidable. Reception of another's report about the world quite obviously involves some kind of grasp of another's linguistic act – another's saying that things are thus-and-so, for example – or the linguistic effects

thereof, such as the written record of another's say-so. Simply put, much of what we believe about the world would be lost without testimony, and without language, testimony would be lost.

Testimony as a Knowledge Source

Reflection on the ubiquity of testimony also highlights the potential importance of language for our felicitous representation of the world. To many epistemologists, testimony plays a central role in affording us not only mere beliefs about but also knowledge of the way things are, where knowledge is distinguished from mere belief at least partly by virtue of requiring justification or derivation from a proper source. (No matter how firmly one believes that supernatural phenomena exist, for example, one's belief that they do fails to amount to knowledge if it is unjustified or derived from an unreliable belief source such as wishful thinking.) As social creatures, Reid (1764/1997: 193) claimed, "We receive the greatest and most important part of our knowledge by the information of others." Echoing the point, Chakrabarti (1994b: 965) notes that "[w]itnesses in law courts, trusted travelers, historians, scientists, dictionaries, radio news-readers, parents, and computers have told us that something is the case and consequently we have come to *know* that it is so."

Skepticism

This common view is by no means universally held. Locke (1689/1989: 58) considered that "[t]he floating of other men's opinions in our brains makes us not

one jot the more knowing, though they happen to be true. What in them was science is in us opiniatrety.” Similarly, Barnes (1980: 200), who acknowledges that “we all do pick up beliefs in [a] second hand fashion,” expresses the “fear that we often suppose that such scavenging amounts to knowledge.” That, he claims, “is only a sign of our colossal credulity: [testimony] is a rotten way of acquiring beliefs, and it is no way at all of acquiring knowledge.”

Skeptics such as Locke and Barnes insist that the most we can get when it comes to the connection between testimony and our representation of the world is the last row of Table 1: Testimony, in their view, can at best generate mere beliefs about the world – that is, beliefs that fail the justification or derivation-from-a-proper-source requirement on knowledge. Others, such as Reid and Chakrabarti, insist that the last row frequently describes a knowledge source: for them, what falls in the output box is often new knowledge of the world.

Even if we grant the importance of testimony for a felicitous representation of the world, we may well wonder how it works. Here, there are three questions to be distinguished. First, how more fully are we to understand the salient input to testimony if it is indeed to be understood as a knowledge source? Second, what, if anything, must be added to the salient input to get the total input to testimony as a knowledge source? Third, how are we to understand the cognitive process that leads from the total input to new knowledge of the world?

Perception and Understanding

Regarding the first question, there is little doubt that sensory perception is involved: In receiving another’s report about the way things are, one comes to know that another has reported that things are thus-and-so on the basis of visual, auditory, etc. experience of the physical items that encode the report. However, bare sensory perception does not suffice. Both the monolingual Japanese hearer and the Anglophone hearer might equally perceive through their senses a speaker’s auditory deliverance ‘I’m

tired today,’ even though only the latter may count as receiving the speaker’s report that he or she is tired today, because only the latter may understand the meaning of the perceived deliverance. Generally, then, the salient input to testimony as a knowledge source amounts to knowledge, acquired through sensory perception of an understood linguistic act (or its effects), that another has reported that things are thus-and-so.

Reductionism and Anti-reductionism

The second and third questions bring us to the heart of the most prominent issue in epistemologists’ attempt to understand the nature of testimony as a knowledge source, viz. the reductionist/anti-reductionist debate. Whereas reductionists (Fricker, 1987; Hume, 1777/1995) maintain that testimony as a knowledge source reduces across the board to a species of inference, anti-reductionists (Burge, 1993; Chakrabarti, 1994a; Coady, 1992; McDowell, 1994; Reid, 1764/1997; Strawson, 1994) demur.

The kind of inference to which testimony as a knowledge source reduces, according to reductionists, is inference from the salient input together with knowledge of the trustworthiness of the reporter with respect to what he or she has reported. Hence, reductionists’ answer to the second question is that knowledge of the trustworthiness of the reporter must be added to the salient input to get the total input to testimony as a knowledge source. Their answer to the third question is that we are to understand the cognitive process leading from testimony’s total input to its output as one of inference. These answers jointly present a model of testimony as a knowledge source that is roughly captured in Table 2.

Anti-reductionists’ answer the second question, in contrast, holds that in many cases nothing must be added to the salient input to get the total input to testimony as a knowledge source. Their response to the third question is that the cognitive process leading from testimony’s total input to its output is better thought of simply along the lines of causation in general, since inference in particular is not required

Table 1 Belief sources

<i>Salient input</i>	<i>Cognitive process</i>	<i>Output</i>
<i>Sensory experience of the world</i> , e.g., having the visual impression of a chair over yonder	<i>Sensory perception as a belief source</i>	<i>New belief about the world</i> , e.g., believing that there is a chair over yonder
<i>Old belief about the world</i> , e.g., believing that Socrates is a man and that all men are mortal	<i>Inference as a belief source</i>	<i>New belief about the world</i> , e.g., believing that Socrates is mortal
<i>Old belief about the world</i> , e.g., believing that it was cold on Tuesday	<i>Retentive memory as a belief source</i>	<i>Old belief about the world</i> , e.g., believing that it was cold on Tuesday
<i>Reception of another’s report about the world</i> , e.g., hearing another say that it’s raining	<i>Testimony as a belief source</i>	<i>New belief about the world</i> , e.g., believing that it’s raining

Table 2 Reductionist model of testimony as a knowledge source

Input	Cognitive process	Output
(a) Knowledge, acquired through sensory perception of understood linguistic acts (or their effects), that another has reported something about the world, and (b) knowledge that the reporter is trustworthy with respect to his or her report about the world	Inference from input to output	New knowledge of the world

Table 3 Anti-reductionist model of testimony as a knowledge source

Input	Cognitive process	Output
Knowledge, acquired through sensory perception of understood linguistic acts (or their effects), that another has reported something about the world	Causation of output by input	New knowledge of the world

(although it may in some cases be present). Thus, the anti-reductionist opts for something like the model given in Table 3.

(Stepping outside of the recipient's cognitive processes, it should be noted, the anti-reductionist requires certain external conditions to be satisfied for the output of testimony as a knowledge source to amount to knowledge. Like the reductionist, he or she requires that what is reported be true; he or she further requires that the reporter in fact be trustworthy with respect to his or her report, even though the recipient need not know that he or she is trustworthy.)

Reductionists claim that the anti-reductionist model lends itself all too easily to something like epistemic gullibility and hence fails to serve as a plausible model for testimony as a legitimate knowledge source. Anti-reductionists point to cases in which it is supposedly clear that the reductionist model does not apply, most notably those involving young children's acquisition of linguistic knowledge. (Such acquisition seems to be in large part testimonial, but, say anti-reductionists, it cannot with any plausibility be regarded as typically involving inference from knowledge of the trustworthiness of reporters.)

Considerations of this sort have tended to shift the focus of the reductionist/anti-reductionist debate to the question of how to understand testimony as a knowledge source for mature cognitive agents, already possessed of the sort of linguistic knowledge just mentioned (Fricker, 1994, 1995).

Summary

Testimony is undeniably a major source of our beliefs about the world, a fact that underscores the centrality of language for our representational capacities. Many maintain that testimony is also a major source of our knowledge of the world, a contention that implies the centrality of language for our felicitous representational capacities. Even granting this contention, however, there is considerable debate about the nature of testimony. Clearly, it involves knowledge, through sensory perception of understood linguistic acts (or their effects), that another has reported that things are thus-and-so. In the reductionist model, it reduces across the board to inference from such knowledge and from knowledge of the reporter's trustworthiness with respect to his or her report. In the anti-reductionist model, no such reduction obtains.

Thought and Language: Philosophical Aspects

E Eaker, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

There is a veritable thicket of philosophical issues waiting to ensnare anyone who reflects on the relation between thought and language. The complexity of this thicket has been further enhanced by the fact that many philosophers have been preoccupied with trying to understand the nature and limits of human thought about the world we inhabit. In fact, philosophical interest in the relation of thought to the world has, to a large extent, motivated philosophical interest in language. For example, consider the proposal that our concepts and the basic structural features of our thoughts reflect the fundamental ontological categories 'out there' in the world. Some philosophers have proposed that by a careful study of language we can obtain a clearer grasp of the structure of thought and therefore a clearer understanding of what the world is like. Others have argued that the last place to look for metaphysical insight is language, thinking it to be a distorting mirror of the world. In addition to these broader metaphysical and epistemological questions – i.e., questions concerning what the world is like and what we can know about it – philosophical interest in language has also been motivated simply by an understandable fascination with the amazing human capacities for thought and language. It has been emphasized time and again that these capacities set human beings apart from the rest of the natural world.

Two of the main philosophical questions that have arisen regarding the relation of language and thought will be discussed here. First, philosophers have questioned the relative priority of thought and language: is thought prior to language (in some important sense

to be defined) or vice versa? How one conceives of the relative priority of thought and language can affect how one approaches the second question: language and thought are both characterized by intentionality or 'aboutness'. When we think and speak, we are connecting with things in the world, and thinking and talking about them. Philosophers have sought to understand this aboutness of thought and language.

The Relative Priority of Thought and Language

Is thought prior to language? That is, is language merely a vehicle by means of which we express our thoughts? Some philosophers have argued (or merely assumed) that the capacity for linguistic expression is a capacity that allows us to communicate our thoughts and that we have an antecedent grasp on those thoughts. If so, one wants to understand what makes the structure of the natural languages well suited to expressing our thoughts. Are thoughts structured in a way similar to the languages that we use to express them? Is language a window onto the mind, so to speak?

Some have answered this last question affirmatively, but think that the reason the structure of human languages reflects the structure of human thought is because the capacity for language is **prior** to thought in some important sense. An extreme version of this view has been held by philosophers who are skeptical about the very existence of mental phenomena, such as thought. They point out that our tendency to attribute thoughts to other individuals depends largely on their capacity to use language. They argue that perhaps this linguistic behavior is all there really is to thought, properly so-called. Some have found this position too extreme, but have nonetheless stressed that thought, properly

so-called, is not possible without the acquisition of a language and that the idea that language merely serves as the vehicle of thought is misguided. I describe a classic 'Cartesian' view of the primacy of thought over language and briefly sketch a thought-skeptical 'behaviorist' response to it, followed by a more nuanced view that recognizes the existence of thoughts, but argues that language is still prior to thought in an important sense. These issues are very much live ones in current research in linguistics, psychology, and philosophy departments, but to avoid some of the complexity and technical vocabulary of more current discussions, I present more classic loci of the above three positions.

The Cartesian View

The following passages from Descartes (1596–1650) represent commonly held views on thought and the relation between thought and language in the early modern and modern period. First, Descartes exhibits the perennial fascination with thought, and by extension language, as that which distinguishes man from beast. Discussing the possibility of automata constructed to look like and mimic the movements of animals and humans, Descartes writes:

[I]f any such machines had the organs and outward shape of a monkey or of some other animal that lacks reason, we should have no means of knowing that they did not possess entirely the same nature as these animals; whereas if any such machines bore a resemblance to our bodies and imitated our actions as closely as possible for all practical purposes, we should still have two very certain means of recognizing that they were not real men. The first is that they could never use words, or put together other signs, as we do in order to declare our thoughts to others. For we can certainly conceive of a machine so constructed that it utters words, and even utters words which correspond to bodily actions causing a change in its organs (e.g., if you touch it in one spot it asks you what you want of it, if you touch it in another it cries out that you are hurting it, and so on.) But it is not conceivable that such a machine should produce different arrangements of words so as to give an appropriately meaningful answer to whatever is said in its presence, as the dumbest of men can do. Secondly, even though such machines might do some things as well as we do them, or perhaps even better, they would inevitably fail in others, which would reveal that they were acting not through understanding but only from the disposition of their organs. (Descartes, 1999)

We see several themes in this passage. It is argued that what separates humans from the other animals is the capacity for thought and reason. This capacity underwrites the linguistic capacity of humans, whose

linguistic behavior cannot be adequately understood as the predetermined, mechanically generated output response to various external stimuli. To describe the human linguistic capacity in such a mechanical way would be to miss the evident fact that humans, but not automata (or nonhuman animals), understand to a significant degree the external stimuli, are able to reason to an appropriate response, and, on making an utterance, mean what they say. Human language is thus fundamentally rooted in human reason, which is in turn an operation of the human mind. For Descartes, the mind is a distinct substance from the body and its workings cannot be explained by the mechanistic laws that govern bodies. Since nonhuman animals have no minds, they can be described in completely mechanistic terms. How can we know this to be the case? Descartes continues:

Now in just these two ways we can also know the difference between man and beast. For it is quite remarkable that there are no men so dull-witted or stupid – and this includes even madmen – that they are incapable of arranging various words together and forming an utterance from them in order to make their thoughts understood; whereas there is no other animal, however perfect and well-endowed it may be, that can do the like. This does not happen because they lack the necessary organs, for we see that magpies and parrots can utter words as we do, and yet they cannot speak as we do: *that is, they cannot show that they are thinking what they are saying*. On the other hand, men born deaf and dumb, and thus deprived of speech-organs as much as the beasts or even more so, normally invent their own signs to make themselves understood by those who, being regularly in their company, have the time to learn their language. (Descartes, 1999)

Again, Descartes emphasizes the priority of thought to language when he characterizes language as essentially a vehicle of thought. What makes a string of noises a use of language is that it expresses what the speaker is thinking. Any real use of language requires that there be understanding, not mere parroting of sounds. Humans, but not magpies and parrots, produce words, and string them together into sentences in a certain way in an act intended to convey their thoughts. Mere strings of sounds, even word-like sounds, and sentence-like strings of them are meaningless unless produced with the intention of conveying thoughts. Descartes seems to presuppose that as humans – creatures with both mind and body – we are essentially endowed with the capacity for thought. If we are unable, for whatever reason, to learn or to produce the spoken or written language of our community, we will nonetheless have thoughts that we might wish to convey and will find some means for doing so.

Behaviorism

Some philosophers in the early 20th century questioned the rich ontology of mental phenomena that was taken for granted by Descartes. A particularly influential school of thought was 'behaviorism'. Not all behaviorists questioned the existence of unseen mental phenomena. Some were simply trying to demarcate what they took to be the appropriate data on which to base a science of psychology. Such 'methodological' behaviorists thought that scientific description of human psychology should focus exclusively on intersubjectively observable phenomena – in particular on behavior, including linguistic behavior. Such behaviorists had a proscription for scientific methodology in the field of psychology, but stopped short of metaphysical pronouncements. An 'ontological' behaviorist, on the other hand, is someone who wishes to give an analysis of mental vocabulary in terms of outwardly observable behavior, without reference to any phenomena that have those qualities thought to be characteristic of the 'mental' – e.g., being immaterial, inner, available as a result of immediate awareness or through 'introspection' and 'private' (i.e., inaccessible to someone else). An ontological behaviorist has a metaphysical bias against admitting the very existence of phenomena thus characterized and seeks to explain what mistakes we are making when we apparently make reference to such phenomena. Behaviorism as a methodological thesis is not necessarily committed to such a strong metaphysical bias. Nonetheless, for all behaviorists there is a strong sense in which language is prior to thought: either mental vocabulary is analyzed in terms of behavior, in particular linguistic behavior, or, in the scientific description of human beings, it is abandoned in favor of description of behavior.

Sellars: Language as a Precondition for Thought

Wilfred Sellars provides a more nuanced view, avoiding a direct confrontation with our rather strong intuitions that there are mental phenomena, while at the same time explaining why language is indeed a necessary precondition for thought and not the other way around. In *Empiricism and the philosophy of mind*, he defends the following revised version of the classical analysis of our common sense conception of thoughts:

[T]o each of us belongs a stream of episodes, not themselves immediate experiences, to which we have privileged, but by no means infallible, access. These episodes can occur without being 'expressed' by overt

verbal behavior, though verbal behavior is – in an important sense – their natural fruition. Again, we can 'hear ourselves think', but the verbal imagery that enables us to do this is no more the thinking itself than is the overt verbal behavior by which it is expressed and communicated to others. ...Now, it is my purpose to defend such a revised classical analysis of our common-sense conception of thoughts, and in the course of doing so I shall develop distinctions which will later contribute to a resolution, in principle, of the puzzle of *immediate experience*. But before I continue, let me hasten to add that it will turn out that the view I am about to expound could, with equal appropriateness, be represented as a modified form of the view that thoughts are *linguistic episodes*. (Sellars, 1997)

At the same time that Sellars wishes to defend a revised version of the view that there are 'inner' thought episodes, he also wishes to defend a revised version of the view that thoughts are linguistic episodes – the crude form of which is behaviorism. To explain what he means, Sellars introduces a piece of 'anthropological science fiction'. He imagines a stage of 'prehistory' in which humans are limited to using a 'Rylean language' – a language whose fundamental vocabulary is composed of terms for public properties and public objects located in space and enduring through time. It has resources for conjunction, disjunction, negation, and quantification; employs the subjunctive conditional; and allows for other 'looser' logical relations that are typical of ordinary discourse. Sellars asks: Would anything have to be added to the Rylean language to allow speakers of it to recognize and talk about themselves as beings that think (as well as having feelings, sensations, and perceptions)?

First, says Sellars, assume that they also have a way of making 'semantical' statements – i.e., statements about the meanings of the terms in their vocabulary, statements about what has been said by the assertion of a sentence, and a general ability to say that the assertion is true or false. If they have these resources, then they are arguably equipped to talk about thoughts – since thoughts share the same characteristics as bits of language. Just as we can say that when we use the expression 'tiger' we are talking about tigers, we can likewise claim to be thinking about tigers. Sellars proposes that we reverse the classical order of explanation and suppose "that the intentionality of *thoughts* can be traced to the application of semantical categories to overt verbal performances" (Sellars, 1997). Clearly, in order to support this proposal, Sellars must provide an account of the aboutness of linguistic expressions – what connects the term 'Tamela' with the individual, Tamela, whose name it is; what connects the term tiger with the

species *Felis tigris*, and by extension with individual tigers; what connects the term ‘hard’ with that property that nails, concrete, and marble have, but which cotton and rabbit fur lack. Also, Sellars must provide this account without making reference either to a speakers’ independent grasp in thought of some thing, kind, or property or to a speaker’s intentions to refer to such a thing so grasped. Note that from a discussion of the relative priority of thought and language, we have moved into a discussion of the intentionality of thought and language. Sellars’s view that language is prior to thought clearly constrains his explanation of the aboutness of thought and language.

Returning to Sellars’s explanation of how speakers might come to talk about inner episodes such as thoughts, recall that Sellars’s mythical Rylean language-speakers’ capabilities include a description of public objects, properties, and relations and the ability to discuss the semantic properties of words and sentences. At some point, they will notice that their fellows exhibit intelligent behavior even though they are not making any assertions. This will lead them, says Sellars, to develop a theory according to which there are inner episodes that are the beginning of a process that usually, though not always, culminates in overt verbal behavior. The model for these episodes will be overt speech and thus what this rudimentary psychological theory will posit will be ‘inner speech’. As it is inner speech, the semantical properties of outward speech will be applicable to it, and so the Ryleans can talk of the inner episodes as having meaning and as being about various public objects. The term ‘thoughts’ could be introduced to name these episodes of inner speech. Insofar as the Ryleans had good reason to posit these thoughts (on the basis of observing intelligent behavior that is performed in silence), it can be assumed that they really do exist, with a nature to be further determined as the ‘science’ develops.

Two questions immediately come to mind about Sellars’s account: One, if the overt verbal discourse is supposed on this theory to be the culmination of a process that begins with inner speech, i.e., thought, does this not take us back to the Cartesian view that overt linguistic behavior serves as a vehicle for the expression of thought? Two, if we are explaining the occurrence of overt linguistic behavior as the result of thoughts and we allow ourselves to talk about the semantic properties – the meaning and aboutness – of thoughts, are we not thereby analyzing the semantical properties of overt linguistic behavior in terms of the semantic properties of thought? In response to the first question, Sellars replies that, on the contrary, this theory “is perfectly compatible with

the idea that the **ability to have thoughts** is acquired in the process of acquiring overt speech and that only after overt speech is well established, can ‘inner speech’ occur without its overt culmination” (Sellars, 1997; boldface added). In response to the second question, he writes, “It must not be forgotten that the semantical characterization of overt verbal episodes is the primary use of semantical terms, and that overt linguistic events as semantically characterized are the model for the inner episodes introduced by the theory” (Sellars, 1997).

Sellars continues with a description of how we come to self-ascribe thoughts. Sellars proposes that a speaker of the Rylean language, S, can be ‘trained’ on the basis of observing his own behavior, to say of himself that he is thinking ‘p’, just as a third party might say on the basis of S’s behavior that S is thinking ‘p’. According to Sellars, speaker S can eventually “be trained to give reasonably reliable self-descriptions, using the language of the theory, without having to observe his [own] overt behavior.” With the spread of such reliable self-ascription of thoughts, the Ryleans will begin to talk of the ‘privileged access’ that each individual has to his or her own thoughts. Now, *prima facie* Sellars’s story might seem to be exactly backward: after all, do we not think of thoughts as the sorts of things that we simply reflect on, things we introspect, and things we know the contents of? Is it plausible that speakers learn a language that has evolved with the expressive power to allow third-person ascriptions of thought, and that speakers then, by extrapolation, extend those concepts to themselves, self-ascribing thoughts and eventually becoming authoritative reporters of their own thoughts?

The problem with this type of objection to Sellars’s myth is that it misses another key aspect of language, according to some philosophers, its essentially public and social nature. The public and social nature of language has been much emphasized by, e.g., Ludwig Wittgenstein, Paul Grice, and Saul Kripke. Sellars defends his picture by pointing out that it stresses the intersubjectivity of thought and the concepts that are used to describe such inner episodes, while not denying the fact that individuals do have privileged access to their thoughts and do make authoritative self-reports using these concepts. Of our use of concepts such as ‘think’, ‘believe’, and ‘fear’, in self-reporting, Sellars writes:

[T]he reporting role of these concepts – the fact that each of us has a privileged access to his thoughts – constitutes a dimension of the use of these concepts which is *built on* and *presupposes* this intersubjective status. My myth has shown that the fact that language is essentially an intersubjective achievement, and is learned in intersubjective

contexts – a fact rightly stressed in modern psychologies of language, thus by B. F. Skinner and by certain philosophers, e.g., Carnap, Wittgenstein – is compatible with the ‘privacy’ of inner episodes. It also makes clear that this privacy is not an ‘absolute privacy.’ For if it recognizes that these concepts have a reporting use in which one is not drawing inferences from behavioral evidence, it nevertheless insists that the fact that overt behavior *is* evidence for these episodes *is built into the very logic of these concepts*. . . (Sellars, 1997)

A Closer Look at the Relation between Thought and Language

We have seen only a sample of the various complex issues that arise when one considers the relative priority of language and thought. A few more questions might help to puncture the level of generality of the discussion thus far. Suppose with Sellars that mental concepts have “built into their very logic” that they are evidenced by overt behavior. What would this show about the primacy of language over thought? Sellars has told a tale in which thought emerges in individuals in a way that depends on their acquisition of a language. If he is right, then it would seem that he has given us a clear sense in which language is prior to thought. However, this is far from clear due to the sketchiness of Sellars’s tale. Work on this topic by Vygotsky and, more recently, Andy Clark has seen the more detailed development of the view that although we do not think in any particular language, the acquisition of a language provides the necessary scaffolding for thought. Some quite recent work by psychologists such as Elizabeth Spelke and Dedre Gentner also address these and related issues. (See, for example, Vygotsky, 1998, Clark, 2003 and Gentner and Goldin-Meadow, 2003.) Returning to Sellars, many questions remain untouched and suggest a much more complicated picture about the relation between thought and language, including the question of intentionality.

First, we might return to that part of Sellars’s myth in which language begins to emerge in a community. Plausibly, the initial steps will involve the introduction of names for particular things, categories of things, properties of things, and relations that they bear to one another. How can this practice emerge if there is not an antecedent awareness on the part of the protolanguage users of individuals as distinct from one another, an antecedent awareness of ways in which things resemble or fail to resemble one another, and so on? That an expression can be introduced for some individual, collection of individuals, kind of substance, or property of things would seem to require an antecedent focus on it. This would suggest

that the aboutness of linguistic items is not fundamental, but is instead derivative from the aboutness of such a prelinguistic focus of the mind.

Second, setting aside speculation into the origins of language, we can simply focus on individuals who are learning a language. In Sellars’s favor, it does seem obvious that learning a language greatly enriches an individual’s thought capacities. If I have no language, I am unlikely to have the concepts that would allow me to think: *The recent convictions of crooked CEOs who hold themselves above the law is symptomatic of the public’s dissatisfaction with the current economic climate*. Nonetheless, consider the true language novice: Perhaps it is necessary for learning terms such as ‘ball’ and ‘mommy’, that a child can already discern in a rudimentary way an object from its surroundings, can distinguish one object from another, can distinguish himself from his mother, and can tell his own feet from toys in his crib. Perhaps some rudimentary conceptual abilities are preconditions for the acquisition of language. These questions are the focus of extensive empirical study and there remains a considerable amount of controversy over the role of language in concept formation and development.

Third, leaving aside the language learner, we can focus on the linguistically competent adult who asserts: *The man in the corner wearing the toupee is Janice’s employee*. What makes it the case that this assertion is **about** some particular individual? Is it simply the fact that some man is standing in the corner indicated by the speaker and is the only such man wearing a toupee? In other words, does the definite description used, and the rules of language that govern how definite descriptions are to be used to refer to individuals by means of their properties, determine who is being referred to? Or are the intentions and mental focus of the speaker also important? Suppose there is a man in the corner but that he is not wearing a toupee. He is, nonetheless, the person to whom the speaker intends to refer. Can we make sense of the speaker having such an intention, independently of her use of a certain description? It would seem unintuitive to deny this. If we agree that it makes sense to say that the speaker **intends** to refer to a particular man, regardless of the description she uses, would we say that the speaker nonetheless **fails** to refer to that man, simply because that man does not fit the definite description *the man in the corner wearing the toupee*? In general, do linguistic expressions and the rules that govern them determine their own path to objects in the world or is the referential role of linguistic expressions parasitic on the more primitive aboutness of our thoughts?

All three of the above paragraphs concern the relative priority of thought and language when it comes to explaining the aboutness of our thoughts and of the 'referring expressions' in our language. But all three focus on a different stage in the development, acquisition, and use of language. Thus, not only the questions, but also the considerations that should be brought to bear in answering them will be different. Though this essay provides but a sampling of the variety and complexity of the issues concerning the relation between thought and language, it should help to explain why philosophers, linguists, and psychologists must spend as much time clearly articulating precisely what questions they are concerned with, as they do in looking for answers to them.

Transformational Grammar: Evolution

This article is reproduced from the previous edition, volume 9, pp. 4650–4664, © 1994, Elsevier Ltd.

Transformational grammar was developed in the mid 1950s by Noam Chomsky. Over the next two decades it became the dominant paradigm in syntactic theory and description and its descendant, government binding theory is still one of the most influential

current theories. Transformational grammar forms a wide-ranging theory, whose central tenets are the use of hypothetico-deductive methodology to construct formal models of certain aspects of human linguistic capabilities. Such models are called 'grammars' in the theory and are taken to be an encoding, in some form, of the native speaker's linguistic knowledge (or 'competence'). Much of the work of transformational grammar has consisted of constructing models of (fragments of) individual languages, but equally important has been the task of exploring and defining

the properties which are required by such grammars to provide accurate and revealing accounts of the linguistic data under consideration. Such general properties are taken to form the content of 'linguistic theory' (also termed 'universal grammar') and therefore do not need to be stated in individual linguistic descriptions. While a grammar for an individual language is a representation of the linguistic knowledge of the native speaker of that language, linguistic theory represents the properties (possibly very abstract in nature) which constrain all languages and thus defines the notion 'possible human language.' The content of universal grammar is taken to be a characterization of the human language acquisition device – those antecedent conditions that make language acquisition possible and which constrain the learning space available to the child acquiring a native language. Transformational grammar has undergone significant evolution since its initial development and one of the slightly ironic consequences of the pursuit of the goals listed above is that transformations themselves have come increasingly to play a less and less significant role in the theory. This article traces that development.

Early Transformational Grammar

Transformations, from which the theory derives its name, were developed during the 1950s by Zellig Harris and Noam Chomsky. The central idea underlying the concept of transformation was that of capturing systematic relationships between different syntactic representations. However, because of fundamental differences in the metalinguistic goals of Harris and Chomsky, the role played by transformations in the work of the two and the consequences of their introduction also were radically different.

Harris on Transformations

For Harris, transformations offered a way of allowing structural linguistics to transcend the limits of the sentence and offer a method of approaching discourse-level structures. For Harris, transformations are a device that extends the descriptive linguistic techniques of segmentation and classification to texts larger than a single sentence. They allow the linguist to establish equivalences between sequences of words in a text which would otherwise resist analysis. For example, suppose that a text contains the sentences:

- (1) He played the cello.
- (2) The cello was played by Casals.

but no sentences of the form:

- (3) Casals played the cello.
- (4) The cello was played by him.

In other words, there are no environments which show that *Casals* and *he/him* are grammatically equivalent (i.e., belong to the same grammatical category).

If, however, the text contains active/passive sentence pairs:

- (5) He plays the guitar.
- (6) The guitar was played by him.

an equivalence can be established between the two sentence types, as follows:

- (7) $N_x V N_y \leftrightarrow N_y \text{ was V ed by } N_x$

Assuming that *He*, *him*, *Casals*, and *the guitar* belong to the category N , and that *played* is a member of the category V , (7) captures the relationship between the two; and between all other pairs of sentences possessing the same structure. With the equivalence given in (7) above, 'we can show that all the environments of *Casals* are equivalent to all those of *he*; and this in turn can make other equivalences discoverable textually' (Harris 1952: 129).

Chomsky on Transformations

For Chomsky, on the other hand, transformations formed part of a program directed at characterizing the nature and properties of the human language faculty. Chomsky states:

The development of these ideas that I would like to report on briefly, however, follows a somewhat different course. It begins by questioning the adequacy of a certain view of the nature of linguistic theory that has dominated much recent work, and it attempts to reformulate the goals of linguistic theory in such a way that questions of a rather different nature are raised. And finally, it attempts to show that the concept of grammatical transformation, in something like Harris' sense, but with certain differences, is essential to answering these questions (Chomsky, 1964b: 212).

One major difference between Chomsky's and Harris's applications of transformations was the nature of the representations between which a transformational mapping held. For Harris, the kinds of relationships captured by transformations were essentially those which in terminology developed later were called 'surface structure' relationships (Chomsky 1965a). That is to say, the mappings defined by transformations were limited to those which could be expressed in terms of the categories and linear order of the actually occurring words/morphemes in a sentence. For Chomsky, no such restriction was applicable. This is apparent in one of Chomsky's earliest and most well-known transformational analyses: that of the English auxiliary system. The abstractness permitted by Chomsky's conception

of transformations allowed him to propose an elegant and simple analysis of the auxiliary system which, in the words of Newmeyer (1980: 24), “[...] probably did more to win supporters for Chomsky than all of his metatheoretical statements about discovery and evaluation procedures.” In *Syntactic structures*, the book in which transformational grammar first became accessible to the linguistic community, Chomsky states:

The study of these ‘auxiliary verbs’ turns out to be quite crucial in the development of English grammar. We shall see that their behaviour is very regular and quite simply describable when observed from a point of view that is quite different to that developed above. Though it appears to be quite complex if we attempt to incorporate these phrases directly into a [S, F] grammar [i.e., a phrase structure grammar] (Chomsky 1957: 38).

and proposes the following phrase structure rules:

- (i) $Verb \rightarrow Aux \rightarrow V$ [28]
- (ii) $V \rightarrow \textit{hit, take, walk, read, etc.}$
- (iii) $Aux \rightarrow C (M) (\textit{have} + \textit{en}) (\textit{be} + \textit{ing}) (\textit{be} + \textit{en})$
- (iv) $M \rightarrow \textit{will, can, may, shall, must}$
- (i) $C \rightarrow \left\{ \begin{array}{l} S \text{ in the context } NP_{sing} \\ \emptyset \text{ in the context } NP_{pl} \\ \textit{past} [29] \end{array} \right\}$

Rule [28iii] states that an *Aux* phrase must contain as its initial element the tense/agreement morpheme *C*, and that this initial element can be followed by zero or more of *M*, *have + en*, *be + ing*, *be + en* in that order. *M* can then take any of the forms in [28iv]. Chomsky (1975: 232–33) observes, however, that:

the sequence of morphemes which results from an application of [28] is not in the correct order. Thus to complete the statement we give the following rule [which later became known as ‘affix hopping’]:

- (ii) Let *Af* stand for any of the affixes *past*, *S*, Φ , *en*, *ing*. [29]

Let *v* stand for any *M* or *V*, or *have* or *be* (i.e., for any nonaffix in the phrase *Verb*).

Then:

$Af + v \rightarrow v + Af \#$

where $\#$ is interpreted as word boundary.

- (iii) Replace $+$ by $\#$ except in the context $v \rightarrow Af$.
Insert $\#$ initially and finally.

When the items *S*, *have + en* and *be + ing* in rule [28iii] are selected to give the string:

- (8) $\textit{the} + \textit{man} + S + \textit{have} + \textit{en} + \textit{be} + \textit{ing} + \textit{read}$
 $+ \textit{the} + \textit{book}$

and rule [29ii] is applied three times (first to $C + \textit{have}$, then to $\textit{en} + \textit{be}$, and finally to $\textit{ing} + \textit{read}$), followed by

the application of rule [29iii], the following is derived:

- (9) $\textit{the} \# \textit{man} \# \textit{have} + S \# \textit{be} + \textit{en} \# \textit{read} + \textit{ing} \# \textit{the} \#$
 \textit{book}

Chomsky’s analysis thus depends upon an abstract structure in which the affixes of the auxiliary system do not appear in their ‘surface’ order. The question of what kind of syntactic representations could legitimately constitute the input and output of a transformation came to be one of the most significant issues in the development of transformational theory.

In Chomsky’s interpretation of the notion, a transformation is a mapping which converts a sentence (= a string of words) with an associated constituent structure analysis (= a ‘phrase marker’), defined by a set of phrase-structure rules, into a new sentence with a ‘derived constituent structure.’ A transformation consists of a ‘structural analysis’ (often also called a ‘structural description,’ and abbreviated to *SD*), which specifies the sequence of categories into which a phrase marker must be analyzable for the transformation to apply to it, and a ‘structural change,’ which specifies the changes effected on the input phrase marker by the transformation. For example, the passive transformation is given by Chomsky (1957: 112) in the following form:

- (10) Structural analysis:
 $NP - Aux - V - NP$
Structural change:
 $X_1 - X_2 - X_3 - X_4 \rightarrow X_4 - X_2 + \textit{be} + \textit{en} - X_3$
 $- \textit{by} + X_1$

(An alternative notation, which merges the structural analysis and structural change into a single statement of the form:

- $NP_1 - Aux - V - NP_2$
 $\rightarrow NP_2 - Aux + \textit{be} + \textit{en} - V - \textit{by} + NP_1$

was also commonly used in later transformational work.)

The structural analysis specifies that for the transformation to apply to a string, the phrase marker associated with that string must be analyzable into a sequence of $NP - Aux - V - NP$. In the structural change, the variables $X_1 - X_4$ identify the four categories listed in the structural analysis and the string to the right of the arrow defines the mapping effected by the transformation: the relative positions of the two NPs are interchanged, the morpheme *by* is adjoined to the left of X_1 in its new position and the morphemes *be* and *en* are adjoined to the left of X_2 (= *Aux*). Each transformation is thus the composition of a number of more elementary operations, which include

deletion, substitution of one element for another, adjunction, and permutation. For example, Chomsky (1965b: 120) specifies the operation of the passive transformation in terms of the following 'elementary transformation,' which details the operations performed by the rule:

- (11) $tp(Y_1; Y_1, \dots, Y_4) = Y_4$
 [substitute Y_4 for Y_1]
 $tp(Y_1, Y_2; Y_2, Y_3, Y_4) = Y_2 \wedge be \wedge en$
 [adjoin *be* and *en* to the right of Y_2]
 $tp(Y_1, Y_2, Y_3; Y_3, Y_4) = Y_3$
 [leave Y_3 unchanged (identity)]
 $tp(Y_1, Y_2, Y_3, Y_4; Y_4) = be \wedge Y_1$
 [adjoin *be* to left of Y_1]
 $tp(Y_1, \dots, Y_n; Y_n, \dots, Y_r) = Y_n$ for all $n \leq r \neq 4$
 [identity]

This notation identifies each term in the structural description of the transformation by successively splitting the structural description into two substrings (indicated in 11 by the semicolon), one of which terminates with that item and the other of which begins with it. For each such item, the elementary transformation specifies what operation is performed on it.

As stated above, Chomsky's motivation for the introduction of transformations was radically different to that of Harris. Chomsky had established a hierarchy of language types, which could be used to model the properties of human languages. Each of the languages on the Chomsky hierarchy is defined in terms of the possible sequences of symbols it admits. Chomsky presented a proof that English possesses properties which mean that it cannot be analyzed in terms of the most restricted type of language on the hierarchy: 'finite state languages.' He also argued that any attempt to describe the syntactic properties of English in terms of the kind of devices available for characterizing the next weakest language type on the hierarchy ('phrase structure languages') leads to the loss of generalizations and greater complexity. The simple and elegant analysis of the English auxiliary system or of the passive outlined above, for instance, which require the capacity to rearrange the order of elements in a string cannot be accomplished within the limits of these more restricted grammatical systems. Chomsky concludes (1957: 44) 'By further study of the limitations of phrase structure grammars with respect to English we can show quite conclusively that these grammars will be so hopelessly complex that they will be without interest unless we incorporate such rules [i.e., transformations].' (It is, however, important to note that Chomsky did not *prove* that English could not be analyzed by phrase structure

grammars at all. Rather, he argued that any such analysis would be unacceptably complex and unrevealing. Indeed, later developments in phrase structure grammars in the 1980s demonstrated that even this assertion is too strong.)

A grammar for Chomsky is a device which defines the language under investigation via a system of rules. In the earliest stages of transformational grammar (e.g., *Syntactic structures*), the grammar consisted of three sets of rules:

- (12) Phrase structure rules
 Transformations
 Morphophonemic rules

As seen above, the phrase structure rules defined the constituent structures which form the input to the transformational component. The morphophonemic rules are responsible for ensuring, for example, that *take + en* is realized as *took*.

Subtypes of Transformations

Transformations in the early period fell into two categories, 'singular' transformations, whose domain consisted of a single sentence, and 'generalized' (or 'double-based') transformations, with a structural description containing reference to more than one sentence. All the examples mentioned so far have been of singular transformations. An example of a generalized transformation is the rule for coordination (Chomsky 1957: 113):

- (13) Structural analysis: of S_1 : $Z - X - W$
 of S_2 : $Z - X - W$
 where X is a minimal element (e.g., *NP*,
 VP, etc.)
 and Z, W are segments of terminal strings.
 Structural change:
 $(X_1 - X_2 - X_3; X_4 - X_5 - X_6) \rightarrow (X_1 -$
 $X_2 + and + X_5 - X_6)$

For example:

- (Yesterday - John - left home; Yesterday - Sam -
 left home)
 \rightarrow (Yesterday - John + and + Sam - left home),
 where *John* and *Sam* are both instances of *NP*.

A further major class of generalized transformations were those that embedded one sentence in another. Chomsky (1964b) lists 19 such transformations, of which the following are representative examples:

- (14) Nominalization
 Structural analysis: S_1 : $T, it + \phi, VP$
 S_2 : NP, C, VP_1
 Structural change:
 $X_4 + S$ or ϕ replaces X_1 ; *ing* + X_6
 replaces X_2

For example:

$$\left\{ \begin{array}{lll} \text{T} & -\text{it} + \text{C} & - \text{be} + \text{a} + \text{great} + \text{surprise} \\ \text{X1} & \text{X2} & \text{X3} \\ \text{John} & - \text{C} & - \text{prove} + \text{the} + \text{theorem} \\ \text{X4} & \text{X5} & \text{X6} \end{array} \right\}$$

→ John + S - ing + prove + the + theorem - C -
be + a + great + surprise

giving 'John's proving the theorem was/is a great surprise.'

(15) Complement

Structural analysis: $S_1: X, V_T, \text{Comp}, NP$
 $S_2: NP, \text{Aux}, \text{be}, \text{Pred}$
 Condition: X_2 is a member of the
 class of verbs
 containing *consider*,
believe, ...
 Structural change: X_5 replaces X_4 ; X_8
 replaces X_3

For example:

$$\left\{ \begin{array}{llll} \text{They} + \text{C} & - \text{consider} & - \text{Comp} & - \text{the} + \text{assistant} \\ \text{X1} & \text{X2} & \text{X3} & \text{X4} \\ \text{the} + \text{assistant} & - \text{C} & - \text{be} & - \text{qualified} \\ \text{X5} & \text{X6} & \text{X7} & \text{X8} \end{array} \right\}$$

→ They + C - consider - qualified - the + assistant

Following the application of an obligatory transformation which permutes the last two factors in the derived phrase marker, this gives *They consider the assistant qualified*.

This class of generalized transformation exemplified by (15) formed the locus of recursion in early transformational grammar, and was thus the mechanism by which grammars make available an infinite set of sentences from finite resources.

Rule Ordering

Transformations, in principle, could be ordered arbitrarily relative to one another (i.e., they were extrinsically, rather than intrinsically ordered). For example, the derivation of an interrogative sentence such as *Did John eat an apple* involved the application of the (optional) question-formation transformation:

(16) Structural analysis: $\left\{ \begin{array}{l} NP - C - V \dots \\ NP - C + M - \dots \\ NP - C + \text{have} - \dots \\ NP - C + \text{be} - \dots \end{array} \right\}$

Structural change: $X_1 - X_2 - X_3$
 → $X_2 - X_1 - X_3$

In other words, the tense formative *C* moves to the front of the sentence. The resulting derived P-marker requires the obligatory application of the word-boundary transformation [29iii] and the *do*-insertion

(17) *do*-insertion

Structural analysis: $\# - Af$
 Structural change: $X_1 - X_2 \rightarrow X_1 - do + X_2$

(Adjoin the word *do* to the left of any affix immediately preceded by a word boundary.)

The successive stages of the derivation would look like this:

Phrase structure: John - C - eat - the apple
 Question-formation: C - John - eat - the apple
 Word-boundary: #C#John#eat# the apple
 Do-insertion: #do + C#John#eat# the apple

(*do* + *C* is then converted to *did* by a morphophonological rule).

In order to correctly derive the sentence *Who ate the apple*, it was necessary to stipulate that T_w , the rule which moves an interrogative element such as *who* to sentence initial position, must apply *after* the question-formation transformation:

Phrase structure rules: John - C - eat - the apple
 Question-formation: C - John - eat - the apple
 T_w : Who - C - eat - the apple
 Word-boundary: #Who#C eat# the apple

Do-insertion cannot apply to this structure, so affix hopping [29ii] applies obligatorily instead:

Affix Hopping: #Who# eat + C# the apple

Applying the two transformations in the reverse order would have the following effect:

Phrase structure rules: John - C - eat - the apple
 T_w : Who - C - eat - the apple
 Question-formation: C - who - eat - the apple
 Word-boundary: #C # who# eat# the apple
 Do-insertion: #do + C# who# eat# the apple

This would give the ungrammatical **Did/does who eat the apple*. The only way in this analysis to avoid the generation of this ungrammatical string is to stipulate the ordering which gives the correct results.

In addition, a stipulation was required as to whether the application of a given transformation was either obligatory or optional. In the examples given above, the passive transformation is an instance of an optional rule, 'affix hopping,' [29ii] an instance of an obligatory rule - it must apply to any structure which meets the terms of its structural analysis. A sentence that is generated solely by the application of obligatory rules was termed a 'kernel' sentence. These corresponded to the class of simple, active, declarative sentences. Associated with the transformational derivation of each sentence was a representation called a 'T-marker,' which recorded which transformations had applied and in which order.

Transformations and Mental Processes

Although transformational grammar is intended as a model of the linguistic knowledge of the native speaker, it was not Chomsky's claim that the components of the theory were a model of the way the construction or comprehension of linguistic utterances is computed in the brain. Nonetheless, a number of experiments carried out in the 1950s and 1960s seemed to show that the transformational grammars developed for English during the early period did indeed make accurate predictions if taken as models of mental processing. In brief, these experiments seemed to show that there was a correlation between the number of transformations involved in the derivation of a sentence and the processing complexity associated with the sentence, measured in terms of some behavioral index such as response time – the greater the number of transformations involved, the greater the processing difficulty. For example, passive sentences take longer to process than their active counterparts and negative sentences take longer to process than their affirmative counterparts.

However, subsequent studies and a more mature assessment of the results of these experiments have shown that those experiments which seemed to show a positive correlation between transformational complexity and processing load did so because of a failure to control for other variables. It is well attested that processing load increases with sentence length. In the case of passive sentences, for example, *Albert was eaten by a lion* is two words longer than *A lion ate Albert*. Once such factors as this were controlled for, it became apparent that the derivational complexity hypothesis could not be maintained. It is universally agreed that the relationship between the form of a transformational grammar and the manner in which it is implemented in the brain is much more abstract and indirect than these early experiments suggested. It is therefore important to note that when linguists talk of a grammar 'generating' a set of sentences, there is no implication in the use of the term that the grammar is a model of human sentence production (see Carroll and Bever 1976).

The 'Standard Theory'

As Chomsky comments (1975: 23), "The theory of transformations developed in *The Logical Structure of Linguistic Theory* was far too unrestricted. It seems that there are much narrower conditions that determine the applicability of transformations and the kinds of mapping they can perform." The subsequent development of transformational grammar can be seen as a progressive transfer of many of the functions

originally assigned to transformations to other components of the grammar.

There are five major areas in which this pattern of development can be seen:

1. Rule interaction;
2. Recursion;
3. Derived constituent structure;
4. The relationship of syntax to semantic interpretation;
5. The degree of abstractness permitted for underlying representations.

Rule interaction had presented a problem in the early theory of transformations because it was not clear what kind of ordering relationships could exist between singular and generalized transformations. It was not clear whether, for example, singular transformations could apply to an incomplete sentence structure *before* a generalized transformation embedded material in it. Various suggestions were made concerning the 'traffic rule' problem, but the most significant contribution was that of Fillmore (1963) who observed that it did not appear that there were any cases in which a singular transformation had to apply to a structure before a generalized transformation embedded material in it. Second, it did not appear that it was necessary in practice to stipulate any ordering between generalized transformations, and third, there were attested cases where a singular transformation could apply to a sentence before it was embedded in a larger structure (passive, for example, in sentences such as *The director believed the keeper to have been eaten by one of the lions*). Fillmore's conclusion from these facts was that singular transformations should apply first to (what would be) the most deeply embedded sentence. This sentence would then be embedded in the matrix sentence by a generalized transformation. This sentence would then become the domain of the singular transformations again, and the process would be repeated as often as necessary.

Since transformations are mappings from phrase markers to phrase markers, it is essential that there be some well-defined way of specifying the constituent structure that results from the application of a transformation. The passive, for example, requires that the word *by* be adjoined to the left of the NP which has been moved into final position. It is clear that the resulting constituent should be a prepositional phrase, and that *by* itself should be a preposition. This information is not derivable, however, from the version of the transformation given above. Some linguists resolved this issue by specifying the details of the derived constituent structure in the structural change of the transformation itself:

$$(18) NP_1 - Aux - V - NP_2 \rightarrow NP_2 - Aux + be + en \\ - V - [_{PP}[_P by] + NP_1]$$

This increasingly came to be considered an undesirable enrichment of the theory and alternatives were sought.

The problem of derived constituent structure also arose in the context of the application of generalized transformations. As can be seen from the complement example above (15), the transformation not only embeds material from one clause into another, but also deletes the subject of the embedded clause. The question then arises as to what the category of the embedded constituent is. The idea rapidly developed (Katz and Postal 1964) that clauses into which a sentence was to be embedded should contain a 'dummy' node, defined by the phrase structure component of the grammar, which would provide a host (and a category) for the embedded material.

These issues were addressed in the 'standard theory,' the name given to the revised version of transformational grammar developed by Chomsky in his book *Aspects of the theory of syntax* (1965a).

Rule Interaction: the Transformational Cycle

In *Aspects* the issues listed above received a radical answer, which reduced the role which transformations played in the theory. Most dramatically, the class of generalized transformations was eliminated entirely and their role as the locus of recursion was allocated to the phrase structure component. The issue of rule interaction was resolved by combining Fillmore's proposals with this innovation. Their joint effect is to require that transformations apply first to the most deeply embedded sentential structure, and, only when all possibilities have been exhausted, is the next 'higher' sentential level considered as a transformational domain. Graphically, the situation is illustrated in the schematic tree in Figure 1.

All transformations apply first to S_2 , then to S_1 , and only then to S_0 . This principle of transformational rule application is known as the ('transformational') cycle.

By way of specific illustration, take the analyses of complementation by Rosenbaum (1967) whose thesis has proved a reference point for most subsequent work. Rosenbaum's work is concerned with the analysis of sentences such as the following:

- (19) Sam prefers to stay here.
- (20) I believe Bill to have been convinced by John.
- (21) John is believed by me to have convinced Bill.

Figure 1

Figure 2

Each of these sentences would earlier have involved a generalized transformation. In the *Aspects* framework, the structures underlying them are provided by the following phrase structure rule:

$$(22) VP \rightarrow V (NP) S$$

This rule preempts the role of generalized transformations by introducing the symbol S on its right-hand side. The structure associated with (19) by Rosenbaum's phrase structure rules (suppressing some details) is given in Figure 2.

On the lowest cyclic domain (the structure dominated by S_1) no rules apply. When the next highest cyclic domain (S_0) is reached, a 'complementizer placement' transformation is responsible for transforming this basic structure into:

Second Cycle: Sam prefers [_{VP} to stay here]]

This structure meets the structural description of what Rosenbaum termed the 'identity erasure transformation' (now generally known as 'equi NP deletion,' or simply 'Equi'):

(23) Equi NP Deletion

Structural Description:

W	(NP)	X	+D	NP	Y	(NP)	Z
1	2	3	4	5	6	7	8

(Where +D identifies the complementizer
for – to.)

Structural Change: 5 is erased (deleted) by 2

The effect of the application of this rule on *Sam prefers [for Sam [VP to stay here]]* is to delete the second occurrence of the NP *Sam*:

Second Cycle: Sam prefers [for [VP to stay here]]

which finally gives *Sam prefers [VP to stay here]]*, through the application of a rule of ‘complementizer deletion.’

For (20) and (21), Rosenbaum’s analysis would provide the derivations in (20a) and (21a). (Note the use of the substructure [MAN by + P] in these derivations to provide a trigger for the passive transformation and a landing-site for the NP moved from subject position by the passive.)

(20a) First Cycle:	I believe [NP it [S [NP John] [VP have + en convince Bill] [MAN by + P]]]
Passive:	I believe [NP it [S [NP Bill] [VP have + en <i>be</i> + en convince [MAN by + <i>John</i>]]]]
Affix Hopping:	I believe [NP it [S [NP Bill] [VP have <i>be</i> + en convince + en] [MAN by + John]]]
Second Cycle:	
Complementizer Placement:	I believe [NP it [S for [NP Bill] [VP to have <i>be</i> + en convince + en] [MAN by + John]]]
Extraposition:	I believe [NP it] [S for [NP Bill] [VP to have <i>be</i> + en convince + en] [MAN by + John]]
Raising to object:	I believe [NP <i>Bill</i>] [S for [VP to have <i>be</i> + en convince + en] [MAN by + John]]
Complementizer Deletion:	I believe [NP Bill] [S [VP to have <i>be</i> + en convince + en] [MAN by + John]]
Post Cycle:	
Morphophonemic Rules:	I believe [NP Bill] [S [VP to have <i>been convinced</i>] [MAN by + John]]

(‘Extraposition’ is a transformation that takes a structure of the form [NP it S] and moves the S rightwards out of the NP.)

(21a) First Cycle:

I believe [NP it [S [NP John] [NP have + en convince Bill]]] [MAN by + P]

Affix Hopping:

I believe [NP it [S [NP John] [VP have convince + en Bill]]] [MAN by + P]

Second Cycle:

Complementizer Placement:

I believe [NP it [S for [NP John] [VP to have convince + en Bill]]] [MAN by + P]

Passive:

[NP it [S for [NP John] [VP to have convince + en Bill]]] *be* + en believe [MAN by + I]

Extraposition:

it *be* + en believe [MAN by + I] [S for [NP John] [VP to have convince + en Bill]]]

Raising:

John *be* + en believe [MAN by + I] [S for [VP to have convince + en Bill]]]

Affix Hopping:

John *be* *believe* + en [MAN by + I] [S for [VP to have convince + en Bill]]]

Complementizer Deletion:

John *be* *believe* + en [MAN by + I] [S [VP to have convince + en Bill]]]

Post Cycle:

Morphophonemic Rules: *John* *is* *believed* [MAN by + *me*] [S [VP to have convinced Bill]]]

In (20a) the passive transformation applies on the first cycle (inside the subordinate clause), whereas in (21a) it applies on the second cycle (in the main clause). In both derivations affix hopping applies twice, once on the first cycle and once on the second. Both these sentences also exemplify the rule of raising (called ‘pronoun replacement’ by Rosenbaum), which moves the subject of a nonfinite subordinate clause (here *John*) into the next higher clause on the second cycle. The existence of this rule was to become a major issue in the subsequent development of transformational grammar.

The Organization of the Grammar

With the adoption of the transformational cycle, many of the problems of rule interaction were satisfactorily resolved and, by the time of the publication of *Aspects of the theory of syntax*, the organization of the grammar took the following form (shown in Figure 3).

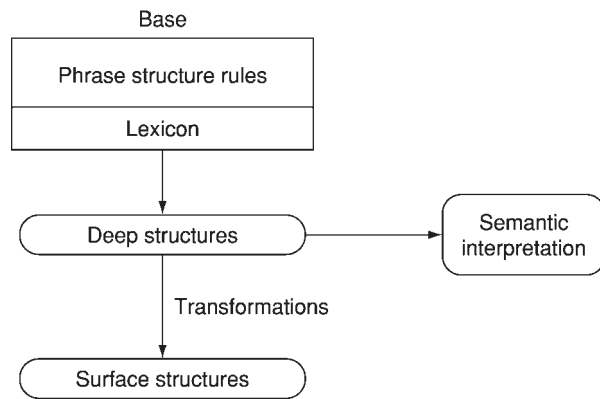

Figure 3

The ‘lexicon’ (formerly part of the phrase structure component) and Phrase Structure Rules were split into separate subcomponents of the ‘base component’ of the grammar and jointly determined a level of syntactic representation called ‘deep structure.’ This, on the one hand, provided the input to rules of semantic interpretation and, on the other, the input to the transformational component of the grammar, which mapped deep structure representations on to surface structure representations in the manner illustrated in (20a) and (21a) above.

Generative Semantics

The proposal that deep structure formed the level at which both lexical insertion and semantic interpretation took place came under strong challenge during the late 1960s. The branch of transformational grammar which became known as generative semantics argued that this conception of the organization of the grammar led to a loss of generalizations, a situation which could be remedied if underlying representations were allowed to be more abstract than Chomsky’s deep structures. This aspect of generative semantics was driven by the Katz–Postal hypothesis (Katz and Postal 1964) concerning the relationship between syntax and semantics. This proposed that all the information necessary for semantic interpretation is represented in the underlying structure of a sentence. Corollaries of this proposal are that synonymous sentences have a single underlying structure and that ambiguous sentences have more than one underlying structure. It also implies that transformations do not change semantic interpretation.

For many sentence pairs, such as actives and passives, this proposal seems eminently reasonable. The assumption that *John saw Bill* and *Bill was seen by John* have the same deep structure and acquire their

Figure 4

different surface forms through the application of transformations provides a basis for accounting for the fact that the two sentences have the same truth conditions. However, this logic, when applied to *Bill is dead* and *Bill is not alive* leads to the conclusion that they too must share a single underlying structure. In this case, however, such an identity in underlying structure must exist *before* lexical insertion, contradicting Chomsky’s hypothesis about deep structure. This led McCawley (1968) to propose that the underlying structure of a sentence of the form *x killed y* should receive the analysis in Figure 4 (note that McCawley is assuming here that in its underlying structure English is verb-initial; see McCawley 1970 for details).

By the repeated cyclic application of an optional transformation of ‘predicate raising,’ the verbs in this structure could be adjoined to one another to give the structure in Figure 5.

McCawley proposed that ‘if lexical insertion did not apply until after that transformation, then the “dictionary entry” for *kill* could be expressed as a transformation which replaces the subtree at the left [of the above tree] by *kill*’ (McCawley 1968: 73). If lexical insertion is constrained to apply before all transformations, as in the *Aspects* approach, the semantic relationship between *x killed y* and *x caused y to become not alive* could not be expressed using transformations.

As an example of ambiguity prompting the postulation of different underlying structures, where purely syntactic evidence might not warrant them, take Lakoff’s (1970) argument that the ambiguity of the sentence (24), with its two paraphrases (25) and (26):

(24) I don’t beat my wife because I like her.

(25) It is because I like her that I don’t beat my wife.

(26) It is not because I like her that I beat my wife.

could be accounted for by the assumption that the two readings correspond to different underlying structures. For (25), Lakoff proposed the structure in Figure 6.

Figure 5

Figure 7

Figure 6

For (26), he proposed the structure in Figure 7.

Transformations called 'it-deletion' and 'neg lowering' apply to these structures to give (24).

A further modification of standard transformational grammar made within generative semantics concerned the nature of the relationship which held between the various levels of a derivation. In standard transformational grammar, transformations are in effect relations between adjacent stages in a derivation. There was no possibility of a transformational 'looking forward' to a future stage in the derivation, for example. Generative semanticists, on the other hand, argued that such extensions were necessary. Lakoff (1971) observed that sentences like *Many men read few books* and *Few books are read by many men* seem to differ in their interpretations. The first is paraphrasable as *There are many men who read few books* and the second as *There are few books that are read by many men*. Lakoff proposed that these two interpretations are derived from different underlying structures. The first has the underlying structure in Figure 8, the second that in Figure 9.

The surface structures are derived by a transformation of 'quantifier lowering.' A problem remains, however, in ensuring that structure in Figure 8 must undergo passive and the structure in Figure 9 must not. Lakoff's solution was to propose that passive and

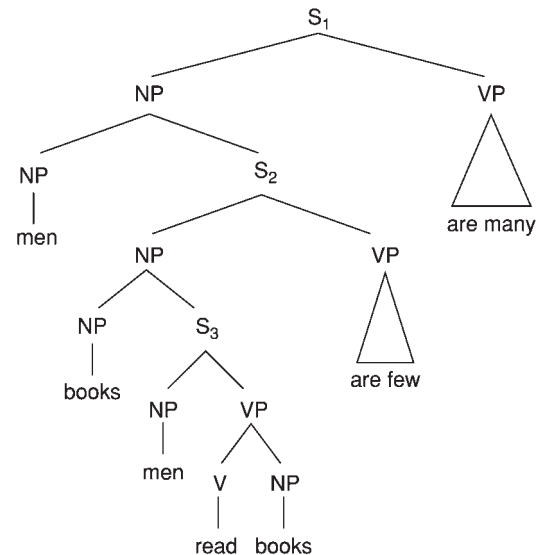

Figure 8

quantifier lowering could freely apply to both structures, but that a 'global derivational constraint' checked the relationship between the underlying and surface forms, requiring that the quantifier which was highest in underlying structure must be the leftmost one in surface structure. Global constraints allow the application of a transformation to have access to any level of representation in the derivation, not merely the information coded in its structural description and structural change.

In essence, what generative semantics did was to pursue the use of transformations to express linguistic regularities and subregularities to its logical conclusion. It assumed that transformations were the *only* way that such regularities should be captured, incorporating into syntactic description phenomena from semantics, pragmatics, and even social interaction. Ultimately, however, this central tenet of generative semantics was rejected by the majority of linguists working in the transformational framework. (A more comprehensive discussion of generative semantics and the factors both linguistic and nonlinguistic

Figure 9

involved in its rise and fall can be found in Newmeyer 1980: ch. 4 and 5.)

The Extended Standard Theory

Subsequent developments in transformational grammar were motivated by a desire to constrain the expressive power of the transformational component. These took two forms. One was to seek to impose restrictions on transformations themselves, with the goal of limiting their expressive power; the other was to reallocate the responsibility for certain classes of phenomena to other components of the grammar, in particular the lexicon, the phrase structure component, and the semantic component. The name given to the version of the theory incorporating these revisions, which developed during the 1970s, was the 'extended standard theory.'

The work of Peters and Ritchie (1973) too undoubtedly encouraged a climate in which constraining the power of transformations was seen as desirable. They provided a proof that transformational grammars of the *Aspects* type had the weak generative capacity of the most powerful device on the Chomsky hierarchy, unrestricted rewriting systems (Turing machines). This meant that human languages, as characterizable by transformational grammars, had no particular properties other than that they could be generated by some set of well-defined rules. *Aspects*-style transformational grammar did not place any interesting constraints on the class of possible human languages. In terms of language acquisition, this implies that the formal properties of transformational grammars provided no interesting restrictions on the search space accessible to the

learner. There was undoubted merit, in the light of these results, in any program which sought to constrain the power of existing transformational grammars.

The Lexicalist Hypothesis

'Nominalization,' referred to above, had been one of the earliest transformational rules proposed (see Lees 1966). Yet in 'Remarks on nominalization,' Chomsky (1970) developed the argument that at least some nominals which had previously been assumed to be transformationally derived were in fact simply basic lexical entries. His argument had two prongs. First, he demonstrated that the basis for the purported generalization was unsound and, second, that there were alternative ways of capturing the generalizations which remained.

In arguing against a transformational analysis of nominalization, Chomsky noted that what he termed 'derived nominals' (such as *refusal*, *easiness*, *revolution*, *belief*) do not occur in structures which are themselves derived by transformations. (The term 'derived nominal' does not imply any transformational derivation. Rather, the term is an allusion to the fact that such nominals form part of the derivational morphology of English.) So the sentences on the right of the arrows in (27) and (29) below are well-formed, but their corresponding derived nominals in (28) and (30) are not:

- (27) To please John is easy \Rightarrow John is easy to please
- (28) *John's easiness to please
- (29) For John to win the prize is certain \Rightarrow John is certain to win the prize
- (30) *John's certainty to win the prize

Furthermore, the semantic relationship which holds between a derived nominal and the item it is supposed to be derived from is frequently idiosyncratic. *John's deeds*, for example, are not the same as *things which John did*, nor is *John's ignorance* the same as *what John ignores*. In the common situation where there is no verb or adjective corresponding to a derived nominal (such as 'book,' 'poem'), the proponent of a transformational analysis is forced to postulate abstract underlying verbs such as *poetize* and to formulate mechanisms to ensure that these nonexistent items do not show up in surface structures (see, for example, Lakoff 1970).

To capture the regularities that do occur, such as *John refused to leave/John's refusal to leave*, *The enemy destroyed the city/The enemy's destruction of the city* and *The city was destroyed by the enemy/The city's destruction by the enemy*, Chomsky proposed first that in cases where there exists a verb/derived

nominal pair, the lexical entry should be neutral with respect to grammatical category, but should specify what complements the pair require. In addition, he proposed an extension of the theory of phrase structure, known as 'X-bar theory,' to allow generalizations to be made across different linguistic categories.

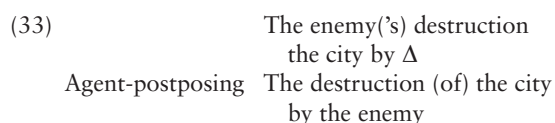

For example, sentences and NPs have a similar internal structure (cf. Chomsky, 1970: 211). In (31) *the theorem* is the direct object of the noun *proof* and *John* is its subject. (This structure also requires the later insertion of the preposition *of*.)

In the corresponding sentence, *the theorem* and *John* hold exactly the same grammatical relations to the verb *prove*.

Chomsky also proposed that cyclic transformations such as passive could apply not only within sentences, but also within NPs, and proposed factoring the passive transformation into two subrules: 'NP-preposing' and 'agent-postposing.' The derivation of *The city's destruction by the enemy* would look like this (with various details omitted):

NP-preposing The city('s) destruction by
the enemy

Note that the intermediate stage, resulting from agent-postposing, is also grammatical, provided that the NP's subject position is filled by a determiner. Exactly the same transformations apply in the case of the sentential passive *The city was destroyed by the enemy*, with the additional proviso that, for independent reasons, NP-preposing is obligatory.

Chomsky's argument, then, was that the generalizations captured by the nominalization transformation were spurious and, to the extent that genuine generalizations exist (such as the existence of active/passive pairs of nominalizations) there are alternative analyses available. The upshot of this was the proposal that transformations cannot change the syntactic category of an item. Thus, the rule of nominalization, as posited in early transformational grammar is not a possible transformation. This proposal was termed the 'lexicalist hypothesis,' because it assumes that any relationship of a crosscategorical kind is represented in the lexicon, and not by a transformational relationship.

Interpretive Semantics

The lexicalist hypothesis removes from the transformational component the power to alter syntactic categories and hence results in the reallocation of one class of linguistic phenomena to another component of the grammar. This is a tendency that is seen to be repeated with respect to other linguistic phenomena as the theory develops.

From the early days of transformational grammar, it had been assumed that the relationship that exists between an anaphoric pronoun and its antecedent, in sentences such as (34), where *Alice* and *she* can be interpreted as referring to the same individual, was to be captured by a transformation:

(34) Alice said that she should go.

The standard analysis of anaphoric pronouns (Lees and Klima 1969) assumed that they were derived from an underlying structure containing two identical occurrences of an NP. One of the NPs would be obligatorily converted into a pronoun by the pronominalization transformation:

(35) Pronominalization
 $X - NP_1 - Y - NP_2 Z \rightarrow X - NP - Y - NP_2 [+Pro] Z$

where $NP_1 = NP_2$ [and various conditions on the topological relations between the two NPs were satisfied].

Jacendoff (1972) argued instead for a treatment of pronominal anaphora which relied on rules of semantic

interpretation (an 'interpretive' approach to pronominalization). Jackendoff pointed out that the condition requiring identity between the two NPs (which must include not only syntactic identity but also identity of reference) is unexpected given that coreference is not generally a condition on the application of transformations; no movement rule, for example, is constrained to apply only to coreferential NPs.

Jackendoff's proposal assumed that anaphoric pronouns were base-generated in underlying structure and that rules of semantic interpretation established the necessary connection between them and their antecedents; no transformation of any kind was involved. This approach had a number of empirical consequences. It provided the basis for a solution to the problem that, in sentences containing quantified NPs such as *every runner*, the transformational treatment of pronominalization predicts incorrectly that *Every runner expects that she will win* should have the interpretation associated with *Every runner expects that every runner will win*.

Furthermore, there are cases of anaphora which do not involve pronouns. Such sentences as *I wanted to help Harry, but the fool wouldn't let me* allow a coreferential interpretation of *Harry* and *the fool*. In addition, the conditions on the configurations in which anaphora is possible are shared by pronominal anaphors and by 'epithets' like *the fool*. For example, neither permit an anaphoric interpretation in sentences like the following *He/the fool said Harry would leave*. It is implausible to envisage a transformation giving rise to epithets, but no problems arise in principle in assuming that epithets are assigned interpretations by the same semantic rules that interpret pronouns. Note also that Jackendoff's proposal is consonant with the lexicalist hypothesis in not allowing a transformation to radically alter the morphological shape of lexical material.

The net conclusion of these and other arguments is that pronominalization is not a transformation and that the phenomenon of pronominal anaphora falls within the domain of the semantic component of the grammar.

Similar arguments apply to two other long-established transformational analyses; those of reflexivization and equi-NP deletion. Reflexivization was assumed to work in complementary distribution with pronominalization; roughly, where the latter applied to identical NPs which were separated by a clause boundary, the former applied to identical NPs in the same clause. Thus, *Mary was proud of Mary* would give *Mary was proud of herself*. Note, however, that when a quantified NP is involved, the result is the same as in the case of pronominalization; *Every runner is proud of herself* does not have the same interpretation as *Every runner is proud of every*

runner. Equi-NP deletion, which derives *Mary wanted to win* from *Mary wanted Mary to win* exhibits the same phenomenon; *Every runner wanted to win* does not have the same interpretation as *Every runner wanted every runner to win*. As a consequence, proponents of the interpretive semantics position argued that neither reflexives nor the control phenomena handled by equi-NP deletion were the responsibility of the transformational component. Instead, reflexive pronouns should be basegenerated and interpreted by the semantic component. For 'equi' sentences it was proposed that the subject position of the nonfinite subordinate clause was filled by a basegenerated phonologically empty pronominal (PRO), also interpreted by the semantic component.

The result of these proposals was the removal from the transformational component of responsibility for a whole class of linguistic phenomena – those involving coreference – resulting in a more constrained theory of transformations and a superior account of the empirical data.

Constraints on Movement Rules

Structure Preservation The lexicalist hypothesis and interpretive semantics reduced the range of phenomena to be accounted for by the transformational component. For those transformations that remained, a major goal of the extended standard theory was to remove from the theory the capacity for individual transformational rules to contain detailed specifications of the conditions of their application, and to replace them with general conditions applying to all transformations, or to whole classes of transformations. This goal may be summarized as that of restricting the expressive power of transformations.

It was noted above that the precise manner in which the derived constituent structure resulting from the application of a transformation was determined was unclear and that various *ad hoc* measures were adopted, such as stipulating derived constituent structure in the structural change of the rule or introducing 'dummy' elements to act as the landing site of a moved constituent. This issue received a more highly-motivated solution in proposals by Emonds (1976). Emonds established three different classes of movement transformations:

(36) Root transformations

Those that crucially involved the root (roughly speaking the topmost) S node, and hence do not apply in subordinate clauses. Examples include Subject–Auxiliary Inversion (*Isn't it cold today*), Directional Adverb Preposing (*Down the street rolled the baby carriage*) and Topicalization (*Our daughters we are proud of*).

(37) Local transformations

Those that involve the reordering of two adjacent constituents, one of which is phrasal and the other nonphrasal. An example is Particle Movement (cf. *She picked up the book* and *She picked the book up*).

(38) Structure Preserving Transformations

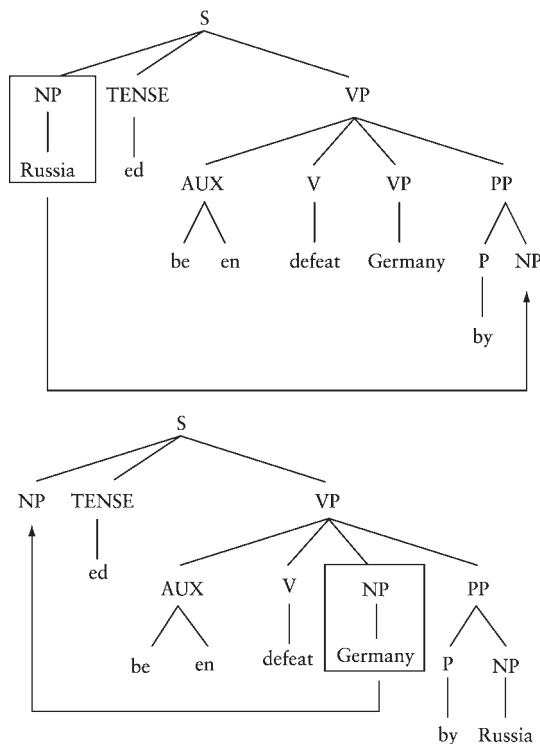

Those that involve the replacement of a node by one of the same syntactic category. Examples include Passive, Raising, There-insertion (*A book is on the table* \Rightarrow *There is a book on the table*) and Dative Movement (*gave a ticket to John* \Rightarrow *gave John a ticket*).

The phenomena handled by root and local transformations have been subject to reanalysis more recently, but the essence of the structure preserving hypothesis has been accepted by all subsequent work.

Emonds argued, like Chomsky, that the passive transformation is in fact a composition of two separate rules: one that postpones the agent NP into the position of *by*-phrase object; and one that preposes the object NP into the vacant subject NP position. This requires that the derivation of *Germany was defeated by Russia* looks like this:

(39)

Agent Postposing:

The structure-preserving hypothesis requires that the *by*-phrase be present in deep structure and that the NP within it be lexically empty (note that this implies that lexical insertion need not take place at deep structure). This analysis accounts for the fact

that the passive *by*-phrase is like any other PP with respect to its internal structure and transformational behaviour.

Emonds points out that the fact that PPs under VP are generally optional in English, when combined with the structure-preserving analysis of passive, accounts automatically for the existence of agentless passives (*Germany was defeated*), in contrast to early analyses which had postulated a rule of *by*-phrase deletion.

Emonds's proposals constituted a step in the direction of removing from the structural description and structural change of a transformation the necessity, or even the possibility, of specifying where a constituent could be moved to; e.g., if the structure involved is not a root S and the transformation does not involve two adjacent constituents, the only possibility is for the moved constituent to move to a location in which the phrase structure rules permit a constituent of that type to be generated.

Blind Application of Transformations The 1970s saw major steps toward the goal of replacing conditions on specific transformations with general conditions which, instead of forming part of individual grammars, were a component of universal grammar. Chomsky (1973) noted that, if the structural description of the passive transformation in English were taken to be essentially:

(41) X, NP, V, NP, Y

with no reference to conditions requiring the two NPs to be members of the same clause (as had been standardly assumed), the transformation would apply to the deep structure analysis of a sentence like *I believe the dog to be hungry*, namely [_S I believe [_S [_{NP} the dog] [_{VP} to be hungry]]] without the necessity for raising to move the NP *the dog* into the higher clause. Without any restriction on its operation, passive (and other transformations) would apply 'blindly' to any structural configuration meeting the structural description. Viewed in this way there is no problem in accounting for sentences such as *The dog is believed to be hungry by me*. Instead, there is a question as to why passive does not apply to *I believe the dog is hungry* to give **The dog is believed is hungry by me*. Chomsky's conclusion was that the failure of the passive to apply to the latter sentence is to be attributed to a general condition on transformational rules to the effect that no item may be extracted from a tensed (finite) clause. This constraint is phrased as follows:

(42) The Tensed-S Condition (TSC)

No rule can involve X, Y in the structure
 ... X ... [_a ... Y ...] ... [where *a* is a tensed sentence]

Chomsky's discussion of reciprocals (*each other*) illustrates the application of the TSC. Following Dougherty (1970), he assumes that *each* in sentences such as (43):

- (43) The men hated each other.

originates in deep structure as part of the subject NP as in (44):

- (44) The men each hated the others.

and is moved out of it by a transformation ('each' movement) to give the structure in (43). The TSC explains why this movement is not possible in sentences like *The men each expected* [_s *the others would win*] to give **The men expected* [_s *each other would win*], and why movement of *each* is possible in the nonfinite counterpart *The men each expected* [_s *the others to win*], giving *The men expected* [_s *each other to win*].

However, given the grammaticality of *The men expected* [_s *to shoot each other*], in which *each* appears in the object NP of the lower clause, the TSC does not account for the ungrammaticality of **The men expected* [_s *the soldier to shoot each other*]. To account for this paradigm, Chomsky proposed the specified subject condition:

- (45) Specified Subject Condition (SSC)
No rule can involve X, Y in the structure
... X ... [α ... Z ... – WYV* ...]. ...

where Z is the subject of WYV in α , α is a cyclic node (NP or S) and α contains a subject distinct from Z and not controlled by X.

'Control' is the relationship which holds between PRO and its antecedent in 'Equi' constructions, or between a 'trace' (see below) and its antecedent. Any subject meeting the additional criterion in (45) is a 'specified subject.'

- (46) We promised Bill [_s PRO to kill each other].

and:

- (47) *We persuaded Bill [_s PRO to kill each other].

In (46) *each* originates in the deep structure as part of the NP containing *we*, which is the controller of PRO and moves into the subordinate sentence by 'each movement' (cf. 44 above); whereas in (47) the controller of PRO is the NP *Bill* which does not contain *each* at any level of representation. PRO in (47) is therefore a specified subject. Note that any phonologically realized NP (such as *the soldier* in (45)) is a specified subject, and also blocks the application of 'each' movement.

Under standard assumptions, there was an immediate counter-example to these conditions: the rule of

wh-movement (so called because it moves phrases which contain the class of interrogatives and relatives that begin with the letters 'wh,' such as *who*, *which*, and *what* – as well as various others not fitting this description, such as *how*). *Wh*-movement is the rule responsible for deriving sentences such as:

- (48) Who did John kill?

Since *kill* is a transitive verb, it is expected to have a direct object, yet no NP follows the verb in (48). The reason for this is that the requirement for an object NP is satisfied at deep structure, and the NP concerned, *who*, is moved to its surface structure position by a transformation.

In contrast to the transformations discussed so far, *wh*-movement has the property of being 'unbounded.' That is to say, that there seems to be no principled limit on the amount of material that can intervene between the deep structure position of the *wh*-item and its surface structure position, as the following examples illustrate (the underscore marks the position from which *who* has moved):

- (49) Who does Max think John killed____?
(50) Who did Sam say Max thinks John killed____?

Note that in these examples the clause which contains the extraction site of *who* is a finite one and, in addition, contains a specified subject (*John*). According to the TSC and SSC these sentences should not be possible.

Chomsky's solution to this problem was the radical proposal that, contrary to appearances, *wh*-movement is a cyclic rule. He adopted a proposal made by Bresnan (1970) that *wh*-movement involves moving the *wh*-phrase into the complementizer position of a clause – roughly speaking, the clause-initial position occupied by *that* or *whether*. This position, known as COMP, has the status of an 'escape hatch' for movement; movement to or from the COMP position does not violate the TSC or SSC.

The derivation of (50) would thus proceed as in (51):

- (51) [_s who [_s did Sam say [_s COMP [_s Max thinks [_s COMP [_s John killed ____]]]]]
- 

To enforce the cyclic application of *wh*-movement (and prevent the movement of *who* in (51) from its deep to surface structure positions in one fell swoop), Chomsky proposed a further condition on movement rules: 'subjacency.' A node X is 'subjacent' to another node Y only if Y is higher in the tree than X and there is at most one cyclic node that dominates X and does not dominate Y. This is illustrated diagrammatically below, where α is a cyclic node (that is, NP or S):

The subjacency condition requires that no movement can take place from X to Y unless X is subjacent to Y. Checking (51) will confirm that the combination of COMP as the landing-site for *wh*-movement and subjacency precludes any other derivation than the one indicated.

Subjacency also provides an account for a class of phenomena known, since Ross (1967), as 'islands.' Despite the apparent unboundedness of *wh*-movement, it had been known for some time that there are constructions out of which *wh*-movement is prevented for some reason from moving *wh*-items. Chomsky (1964a) had observed that while the sentence *John kept the car in the garage* is ambiguous (meaning either that the car in the garage was kept by John, or that the car was kept in the garage by John), the sentence *Which car did John keep in the garage* is not, having only the latter reading. The nonexistent reading is the one in which the NP *the garage* is contained within the larger NP *the car in the garage*. Chomsky had proposed that in a situation like this, where a transformation might in principle apply to either of two NPs, in fact it must apply only to the larger one. This proposed constraint he termed the 'A-over-A principle.'

Ross (1967) gave a detailed investigation of a wide range of situations in which the application of unbounded movement rules was blocked. Ross pointed out that the A-over-A principle proved too strong in certain cases and identified the defining characteristics of the phenomenon as a set of structural configurations which he termed 'islands,' and proposed a corresponding set of 'island constraints' to restrict the application of unbounded movement rules:

(52) Complex NP Constraint (CNPC)

No item may be moved out of a complex NP by transformation, where a 'complex NP' is a structure of the following form.

Example:

Max met a man that sells books/what

*What did Max meet [NP [NP a man] [_S that sells —]]

(53) Sentential Subject Constraint

No item may be moved out of a sentential subject by a transformation.

Example:

That John gave the book to Max/who surprised Sam

*who did [NP [_S that John gave the book to —]] surprise Sam

(54) Coordinate Structure Constraint (CSC)

No conjunct in a coordinate structure may be moved, nor may any item in a conjunct be moved out of that conjunct.

Example:

Max spoke to Sam/who and Fred

*Who did Max speak to [NP — and Fred]

(55) Left Branch Condition

No NP on the left branch of another NP may be moved out of that NP.

Example:

You read Fred's/whose book

*Whose did you read [NP — book]

The subjacency principle serves to provide a unified account of all these island phenomena except the coordinate structure constraint. Note that in all other cases but coordinate structures, the movement involves a violation of subjacency. To illustrate with the last example, in **Whose* [_S *did you read* [NP — *book*]] two cyclic nodes, S and NP, intervene between *whose* and the extraction site.

Chomsky also proposed that subjacency would account for the prohibition on moving two (or more) *wh*-phrases out of the same clause (the *wh*-island constraint), as in **What* [_S *do you wonder* [*who* [_S — *saw*—]]]. On the assumption that, once the COMP node of the lower clause is occupied by *who*, it is no longer a possible landing-site for *what*, the only route to the topmost COMP will involve crossing two S nodes – a subjacency violation.

Trace Theory

The developments outlined in the preceding sections resulted in a situation where the substantive content of transformations had been severely reduced. Lexicalism had removed many linguistic phenomena from the domain of the transformational component, as had the reanalysis of phenomena

involving coreference; structure preservation reduced the need to specify details in the structural descriptions of transformations, and subadjacency limited the domain of application of transformations.

Chomsky (1973) had introduced the idea that movement of an NP left behind a 'trace' of itself. He developed this idea further (Chomsky 1976). He proposed that all movement transformations leave behind an phonetically empty copy (a 'trace') bound by the moved constituent and inheriting all its relevant properties. He points out the pattern of reciprocal interpretation (now effected by an interpretive rule, rather than the transformation of 'each' movement) supports the postulation of such an empty category in sentences involving raising to subject. There is a parallel between (56) and (57), where reciprocal interpretation in (57) allows *each other* and *the men* to be construed together, just as if they were in the same clause, as in (56):

(56) The men like each other.

(57) The men seem to John [*t* to like each other].

There is a similar parallel between (58) and (59), where reciprocal interpretation is blocked by the SSC. This insight is captured explicitly by the occurrence of a trace of NP preposing in (57) which participates in the interpretation of *each other* and one in (59) which forms a specified subject since it is bound by the singular moved NP *John*, blocking reciprocal interpretation with *men* just as the overt occurrence of *John* does in (58):

(58) The men want [John to like each other].

(59) John seems to the men [*t* to like each other].

Lasnik (1977) drew a parallel between the relationship which exists between traces and their binders and that which exists between PRO and its controller and between a reciprocal and its antecedent: always the binder must precede or asymmetrically 'command' the trace. (A commands B if the first S node that dominates A also dominates B.) This means that movement must always be leftward or to a higher position in a tree. Hence, raising is a possible movement rule, but its inverse, 'lowering,' would not be. Similarly, *wh*-movement must always be to a higher COMP node and never to a lower one.

With these developments, Chomsky proposed a constraint on transformations to the effect that the only categories that may be explicitly mentioned in a structural description are those that are changed (i.e., moved, deleted etc.) by the rule. He also suggests that a further step can be taken in the light of the structure preserving hypothesis, which entails that, for example, an NP can only be moved into another

NP position. 'Thus the rules in question [e.g., passive] reduce to the following formulation: move NP' (Chomsky, 1976: 313).

All other details of the operations carried out by the rule are determined by general principles. The landing site being determined by a combination of the structure preserving hypothesis, subadjacency, and Lasnik's condition.

This move was accompanied by a reinterpretation of the status of conditions like the TSC and the SSC, which ultimately spells the end of transformation grammar as such and its evolution into government-binding theory. At their inception, these conditions were construed as constraints on rules, blocking their application. Chomsky now proposed construing them as conditions on surface structure wellformedness. That is to say, 'move NP' can apply freely, but the resulting representations must satisfy the TSC and the SSC. To take a specific example, *John seems [t to like Bill]* is the result of move NP and the trace is bound by an NP (*John*) as required by Lasnik's proposal. In **John seems [Bill to like t]*, although NP movement has applied, the resulting configuration violates the SSC, on the assumption that the relationship between an NP and its trace is just like the one that holds between a reciprocal and its antecedent. The trace does not stand in the appropriate relationship to *John*, any more than *each other* does to *they* in **They expect [Bill to like each other]*.

In 'On binding' Chomsky (1980) took this development a stage further and proposed that the SSC (renamed the 'opacity condition') and the TSC (renamed first the 'propositional island condition,' or PIC, and then the 'nominative island condition,' or NIC) should be reinterpreted as constraints on the occurrence of anaphors alone, rather than as relations between anaphors and their antecedents. The opacity condition took the form 'if α is an anaphor in the domain of the subject of β , β minimal, then α cannot be free in β , $\beta = \text{NP or } S'$ '. The nominative island condition took the form: A nominative anaphor cannot be free in S' . 'In the domain of' means 'c-commanded by,' where A c-commands B if the first branching node which dominates A also dominates B (a revision of Lasnik's 'precede or command'). 'Free' means not coindexed with a c-commanding antecedent. Nominative case is assigned only to the subjects of finite clauses.

To take up the analysis of *each other* to exemplify the revised framework, Chomsky suggests that all that need now be said about the distribution of *each other* is that it is a reciprocal. From this, within an appropriately articulated theory of grammar, will follow the requirement that it be bound by a plural antecedent within the same S' or NP, if it is not itself

a subject, so that (60) is grammatical with *each other* bound by *the students* within the minimal *S'*:

- (60) John expected [_{S'} the students to like each other].

(61), however, is ill-formed, because *each other* has no acceptable antecedent within *S'*:

- (61) *The students expected [_{S'} John to like each other].

(62) is ill-formed because the lower clause is finite. Its subject *each other* is therefore nominative and, according to the NIC, must be bound in *S'*. But, in this structure there is no possible c-commanding binder within *S'*, so the sentence is defined as ungrammatical:

- (62) *The students expected [_{S'} to each other would to like John].

Earlier, Chomsky (1977) had argued that what had been considered a range of different transformations should all be interpreted as expressions of *wh*-movement. These included not only *wh*-questions and relative clauses, but also topicalization (63a) (and its associated analysis in 63b), *Tough*-movement (64a) and (64b), comparatives and cleft sentences, although most of these do not occur with overt *wh*-phrases in them:

- (63a) This book, I asked Bill to get his students to read.
 (63b) [_{S'}^{TOP} This book] [_{S'}^{COMP} what I asked Bill to get his students to read t]].
 (64a) John is easy for us to please.
 (64b) John is easy for us [_{S'}[who for] PRO to please t]].
 (65a) John is taller than Mary is.
 (65b) John is taller than [_{S'}[what] Mary is t]].

Chomsky's argument was founded on the claim that all these constructions exhibit the defining characteristics of *wh*-movement:

- (66) a. it leaves a gap;
 b. there is an apparent violation of subadjacency, PIC and SSC;
 c. it observes the complex NP constraint;
 d. it observes *wh*-island constraints.

For example, the comparative in (67) and the *wh*-question (68) both demonstrate a violation of the complex NP constraint, while the comparative in (69) and the *wh*-question (70) both demonstrate parallel violations of the *wh*-island constraint:

- (67) *Mary is taller than (what) Bill believes [_{NP} the claim that she is –].
 (68) *Who does Bill believe [_{NP} the claim that she met –].

- (69) *Mary is taller than (what) [I wonder [whether she used to be –]].

- (70) *Who [does Bill wonder [whether she met –]].

The set of transformational movement rules was now reduced to two: 'move NP' and 'move *wh*' and in *On binding* Chomsky proposed that it could be reduced still further to 'move α ,' where α is some category of the grammar. Move α will apply freely, but the resulting structures must satisfy the relevant constraints.

Transformational grammar, as it had been envisaged originally, was about to evolve into a theory in which transformations themselves played a relatively minor role. The task of specifying the operations which transformations were entitled to perform was to be replaced by the task of specifying well-formedness conditions on the representations which resulted from the operation of transformations and other kinds of rules. The only constraint specific to transformations was, and remains, subadjacency.

Transformational grammar constituted a major breakthrough in the investigation of the syntax of human languages and spawned an unprecedented amount of research, providing many new insights into language and its structure. It has been a topic of controversy since its inception, and a variety of alternatives now exist which challenge the very bases of transformational theory; but it is fair to say that many of them have developed in response to positions articulated within transformational grammar and it is doubtful that they would have come about without the stimulus and insights provided by transformational grammar. It is certainly true that our understanding of human language would be much impoverished had it not existed.

Truth Conditional Semantics and Meaning

E Lepore, Rutgers University, Piscataway, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

From the early 20th century, beginning with the revolutions in logic begun by the German mathematician Gotlob Frege and the English philosopher Bertrand Russell, until the present, philosophers have speculated about the notion of meaning. A variety of such notions are in general use: natural meaning, as in 'smoke means fire' or 'those spots mean measles'; conventional meaning, as in 'a red traffic light means stop' or 'a skull and crossbones means danger'; intentional meaning, as in 'John means well,' or 'Frank means business.' Philosophical semanticists are preoccupied with a different notion of meaning, however: Linguistic meaning is involved in the utterances of 'the words "bachelor" and "unmarried man" are synonymous (have the same meaning)'; 'the word "bank" is

ambiguous (has several meanings)'; 'the string of words "colorless green ideas sleep furiously" is anomalous (has no meaning whatsoever)'; 'the sentence "All bachelors are unmarried" is analytic (true in virtue of its meaning alone)'; and more directly, 'what "La neve e' bianca" means is that snow is white.'

One problem surrounding linguistic meaning concerns its dual roles. The meaning of a word reaches out, as it were, into the world, but also retains an inwards relation to other words. The meaning of 'tomato' is related both to the world – tomatoes – and to other words it combines with, as in, 'Tomatoes are a fruit'; 'Are tomatoes a fruit?' 'Get me a tomato!' Whatever else meaning involves, these two diverse roles are essential. For if one knows the meaning of 'tomato,' one grasps how it applies to the world and also how to employ it in indefinitely many sentences – a phenomenon labeled the productivity (or creativity) of language.

Compositionality is invariably invoked to explain productivity: the meaning of a complex linguistic expression is a function of the meanings of its parts. Differences in meaning between 'A tomato is better than an apple' and 'An apple is better than a tomato' are due solely to the manner in which the sentences are composed. In this regard linguistic meaning differs from other sorts of meaning. A red skull and cross-bones doesn't mean *stop danger*; smoky spots don't signify *enflamed measles*; if John both means well and means business it doesn't follow he means good business.

Finite beings never have entertained nor will entertain or use more than finitely many sentences, but just as 'A tomato is better than an apple' and 'An apple is better than an orange' are sentences, so too is 'A tomato is better than an apple and an apple is better than an orange'; and just as 'The apple is rotten' is a sentence, so too is 'The apple that fell on the man is rotten,' 'The apple that fell on the man who sat under a tree is rotten,' and so on with no obvious end. Because our language includes devices of grammatical conjunction and relative clause construction, we are able to form new sentences from old ones. Whatever meanings are, they must fit together in accordance with the compositionality principle. The project becomes to settle on basic word meaning and to let sentence meaning be composed from simpler components.

Philosophers have tended to fix on one of the two main aspects of meaning to the detriment of other. A theory of meaning – a semantic theory – must explain how a word can perform both of its functions. So, for example, John Locke, the 17th century empiricist, concentrated on the inner aspects of meaning. For him meaning is mental; we use language to encode thought. Successful communication involves correctly decoding words heard into their corresponding associated ideas. So construed, the meaning of an expression is the idea associated with it in the mind of anyone who knows and understands the expression.

But focusing on inner aspects of meaning raises some issues. Suppose your idea of grass is associated in your mind with your idea of warm weather; would it follow that 'grass' has the idea of warm weather as part of its meaning, at least for you? This focus also ignores the public nature of meaning. We learn the meaning of words from others, and once conversant, we can determine whether others successfully understand us. If meaning is an associated idea, how does anyone learn it? Then there is the matter of compositionality. Suppose a speaker associates with the complex expression 'brown cow' the idea of fear; he is not, however, fearful of cows or brown things *per se*, only the brown cows. On an ideational semantics, the

meaning of 'brown cow' is not predictable from the meanings of its parts.

In an effort to render meaning public, B. F. Skinner hypothesized that the correct semantics for a natural language is behavioristic: the meaning of an expression is the stimulus that evokes it or the response it evokes, or a combination of both, at the time it is uttered. The meaning of 'Fire!' might be as it were to run. But a fireman, or a pyromaniac, or an audience of a known liar or a play doesn't run when she hears 'Fire!' Does it seem plausible that such individuals mean something different by 'Fire!' than those who run do? Then too there is the persistent worry over compositionality. Suppose a speaker recoils when he hears 'brown cow' but not when he hears 'brown' or 'cow' alone. The terms' meaning then would be undetermined by the meanings of its parts. How then does a speaker learn its meaning and the meaning of indefinitely many other expressions that can host it?

Bertrand Russell, following J. S. Mill, pursued the intuition that linguistic items are signs of something other than themselves. He suggested that the meaning of an expression is what that expression applies to, thus removing meaning from the minds and bodies of its users and placing it squarely in the world. On a referential semantics, all that one learns when one learns the meaning of 'tomato' is that it applies to tomatoes, and to nothing else. The semantics is compositional: if 'red' applies to anything red and 'tomato' applies to any tomato, 'red tomato' applies to red tomatoes.

But what about words that apply to nothing, like the term 'unicorn'? What about the serious problem first pointed out by Frege, that two expressions may have the same referent without having the same meaning? For example, 'Samuel Clemens' and 'Mark Twain' name the same author, but they aren't synonyms. As Frege noted, one could believe that Mark Twain wrote *Tom Sawyer* yet disbelieve Samuel Clemens did, without being irrational. Some authors, e.g., J. S. Mill and S. Kripke, conclude that proper names lack meaning. After all, if one does not know the referent of a name, one does not reach for a dictionary but rather an encyclopedia. But the problem persists even for common nouns – paradigmatic meaningful expressions. The descriptions 'the 41st president' and 'the husband of Hillary Clinton' apply to the same person but are not synonymous. One can understand both without recognizing that they apply to the same individual. But if meaning is what one learns when one learns an expression and if meaning is reference, then we have a problem.

In the seminal semantic theory of Frege, inner and outer aspects of meaning are inextricably bound.

Frege associates with each expression a referent. The referents of these parts contribute systematically to the truth or falsehood of sentences in which they occur. Thus the truth or falsehood of 'The 41st president is a Democrat' is determined by the referents of its individual words and the way they are put together. Its overall significance is fixed by what the parts of the sentence 'stand for' in the world and by relations between those parts. It follows that if a word is replaced in a sentence with another having the same referent, its truth or falsehood will not change. So the outer condition is secured. But now worries about the inner aspects of meaning arise. If you believe that the 41st president is a Democrat, it doesn't follow you will believe that the husband of Hillary Clinton is one. So 'You believe that the 41st president is a Democrat' will be true, while 'You believe that the husband of Hillary Clinton is a Democrat' will be false. If meaning determines truth or falsity, meaning must involve more than reference.

Frege accounts for this problem with senses. The sense of an expression is, intuitively, not what is referred to by an expression but the way in which it is referred to. Each sense determines one reference, but to one reference there may correspond many senses. Central to his view is that senses are abstract objects and not ideas in people's minds as per Locke. The two belief sentences above can disagree in truth value because, although both are about Bill Clinton, they pick him out in distinct ways.

Frege doesn't address how we explain the reference of words. A natural albeit vague answer is in terms of the psychological capacities of users of a language: words mean what they do because of what speakers do with them. An example of this semantics is the logical positivism of the Vienna Circle in the 1920s and 1930s, according to which the meaning of a sentence is given by an account of what it would take to verify it.

The basic idea behind verificationism is that meaning must be a result of links between language and experience: some sentences have meaning because they are definable in terms of other sentences, but ultimately basic sentences, the observation sentences, have their meaning because of their direct connection with experience (in this case being reports of it rather than copies). The connections between the world and language come down to a connection between observation sentences, on the one hand, and experience, on the other. Speakers, then, refer to whatever objects they would identify as the referents, whether by description or by recognition. Although the circumstances under which 'triangular' and 'trilateral' apply are the same, speakers go about *verifying* those applications in different ways. This suggests

that the meaning of an expression is determined by the verifiability of sentences containing it.

The case against verificationism was most ardently pressed by W. V. Quine in the 1950s. He followed the verificationists in linking meaning to experience, but he argued that experience relates not to individual sentences but to whole theories. Since meaning must be empirically available, Quine poses the question: What empirical evidence determines what certain utterances mean? He contends that the only acceptable evidence is behavioral, based on the demands of the publicity of meaning, and therefore shuns Fregean senses. But behavioral evidence cannot, he argues, determine whether a person's words mean one thing or another; alternative incompatible 'translations' of the evidence are always available. And so Quine infers his famous doctrine that translation is indeterminate: no facts determine what words mean, i.e., there are no meanings.

Confronted with the skepticism about meaning produced by the indeterminacy of translation (and the later Wittgenstein's work as well), Donald Davidson in the 1960s and 1970s made a significant effort to resuscitate meaning. Sharing Quine's sympathies with an outer criterion, Davidson attempted to account for meaning not in terms of behavior but on the basis of truth, which by then had come to seem more logically tractable than meaning due to the formal work of the Polish logician Alfred Tarski. In the 1930s Tarski defined truth for formal languages in terms of the relation of satisfaction holding between the parts of sentences and sequences of objects. Truth is thereby determined systematically by the satisfaction of sentential parts; Tarski could show how to formally derive, from axioms and rules, semantic theorems that specify conditions under which any sentence of the language is true.

Frege and Davidson agree about compositionality being non-negotiable, but Davidson spurns the troublesome notion of sense and instead employs a Tarskian theory of truth to 'serve' as a theory of meaning. In outline, his idea is that a semantic theory for a language should entail for any sentence a theorem that 'gives its meaning' while respecting compositionality. But how can we devise a semantics with these consequences? Davidson's insight was to replace 'means that' in a sentence like "La neve e' bianca" means that snow is white' with 'is true if and only if.' Tarski had already shown how to prove such theorems. By exploiting Tarski's theory of truth as a semantic theory, Davidson rendered substantive the rough but venerable idea that to give the meaning of a sentence is to give its truth conditions.

But how can a truth conditional semantics explain away the phenomena for which Frege invoked senses in order to explain in the first place? The sentences

'The 41st president is a Democrat' and 'The husband of Hillary Clinton is a Democrat' share truth conditions; both are true just in case Bill Clinton is a Democrat. But they don't mean the same. In response, Davidson suggested that in order to devise an adequate truth theory for any given speaker who uses these sentences, we must apply the constraints of radical interpretation, particularly, the 'principle of charity' – assume that on the whole speakers are truthful. Interpretation proceeds as follows: collect sentences a speaker 'holds true,' and devise a truth theory with theorems specifying the circumstances under which these sentences were held true as a consequence. According to Davidson, any such theory will prove a sentence like "The 41st president is a Democrat" is true if and only if the 41st president is a Democrat,' but not "The 41st president is a Democrat" is true if and only if the husband of Hillary Clinton is a Democrat', thus solving Frege's problem.

Most semanticists in the 1980s and 1990s doubted whether a truth theory could specify the meaning of any given sentence. Many recommended adding to a truth conditional approach a conceptual role (also cognitive role, computational role, and inferential role) semantics. To understand how and why, consider the following thought experiment: suppose each of two otherwise psychologically indistinguishable speakers says, 'I am 30 years old.' The references of their utterances of 'I' differ. This shows that if the meaning of 'I' is what each speaker who uses the word grasps, then meaning does not determine reference. For if meaning determines reference, then these speakers do not grasp the same meaning and therefore they must assign distinct meanings to 'I.'

Hilary Putnam and David Kaplan independently explain this phenomenon by distinguishing the character (or stereotype) of an expression from its referent in a context of use. The character of 'I' maps any context of use onto its user. This character is grasped by anyone who understands the sentence. The utterance's content is its truth condition. When each speaker says, 'I am 30 years old,' what they know may be the same – they have the same understanding – but what each says has different truth conditions.

So far two expressions can share the same character (or stereotype or whatever corresponds to what we know in virtue of which we understand) and yet these expressions can differ in reference and truth conditions, since, as we saw above, conversely, sentences with the same truth conditions, our Bill Clinton sentences, can differ on the understanding component of meaning. What are we to make of someone who understands both sentences, yet asserts the first while denying the second? We know Frege's solution appeals to senses, and we touched upon Davidson's effort with

radical interpretation. The conceptual role semanticist argues, instead, that these two descriptions have distinct computational roles for the speaker.

In sum, there are two distinct ways of semantically individuating a speaker's words: according to truth conditions **and** according to computational roles. According to the way of truth conditions, the speaker believes that Bill Clinton is a Democrat and also believes he is not a Democrat. But his rationality is not impugned, since truth conditions do not exhaust understanding. According to computational role, the corresponding beliefs expressed by utterances of these sentences are distinct, since the descriptions have distinct computational roles. When his beliefs are individuated in terms of computational roles, he does not have contradictory beliefs.

While the idea of a conceptual role for an expression has been around in philosophy for some time, what they are and what form a theory of conceptual role is supposed to take is much less clear than the form of a truth theory. For conceptual role semantics to explain how your word 'tomato' and mine can be synonymous, our words must share conceptual roles, but this is extremely unlikely. As long as there is the slightest difference between us with respect to inferences we are prepared to draw from our word 'tomato,' their conceptual roles differ. But then it is difficult to see how sense could be made of communication. If we assign different meanings to 'tomato' because our conceptual rules are distinct, there is nothing in common to be communicated. If we assign the same meaning (and so, assign the same conceptual roles), there is no need for communication. Compositionality is no easier to understand with conceptual role semantics: the inferential roles of complexes need not be determined by the inferential roles of its components – take 'brown cow' again.

For Davidson, belief and meaning are interdependent. One of the lessons he draws is that nothing can genuinely have beliefs unless it also has a public language. Many philosophers have recoiled, both because they think it is undeniable that certain non-linguistic creatures – such as dogs and apes – have beliefs, and because they hope meaning can be explained in terms of beliefs and other mental states. One such influential semantics is H. P. Grice's, who suggested that the meanings of sentences can be reduced to a speaker's intention to induce a belief in the hearer by means of their mutual recognition of that intention.

Grice's analysis of meaning consists of various parts. It begins with a notion of speaker meaning: A speaker S means something by an utterance if and only if S intends the utterance to produce an effect in an audience A by means of A's recognition of this

intention. So, e.g., I discover a person so constituted that, when I tell him that whenever I groan in a certain way I wanted him to wink; thereafter, whenever he recognizes the groan (and with it my intention), he winks. Grice's underlying idea is that I did something ('made a groan') with intentions. First, I intended to produce the utterance (the groan); second, I intended my audience to recognize the utterance; third, I intended that they should recognize my intention to produce the utterance; and fourth, I intended that they should recognize that I intended them to form some new belief (or do some action, etc.). In these circumstances, according to Grice, my groan means to wink. The place of conventional meaning in Grice's conception of language appears to be that it constitutes a feature of words that speakers might exploit in realizing the intentions referred to in the analysis of speakers' meaning.

Although Grice's program is not as popular as it once was, the general idea of reducing meaning to the psychological states of speakers is now widely accepted (*contra* Quine, Davidson, Wittgenstein, and their followers). In this sense Griceans have returned to the 17th century's emphasis on inner

over outer aspects of meaning. How much, in the end, semantic properties can be attributed to features of the human mind remains a deep problem for continued study.

Truth: Primary Bearers

Introduction

What are the kinds of thing that are capable of being true or false – of bearing a truth-value? This issue in metaphysics connects with central issues in the philosophy of language. As noted in Haack (1978: 79), it has been regarded as bearing on such topics as the semantic paradoxes, the motivation for many-valued logics, and the viability of Russell's theory of descriptions.

To judge by our loose talk, various kinds of thing are capable of bearing truth-value. The obvious candidates are sentences, statements, propositions, and beliefs. Suppose Sally asserts the English sentence (1):

- (1) George W. Bush was president of the United States in 2003.

We might describe her as having made a true statement, as having (assertorically) uttered a true sentence, as having expressed a true proposition, or

as having given voice to a true belief. But supposing that we regard truth and falsity as properties, might it not be the case that 'in the final analysis' only one candidate has these properties nonderivatively?

Consider for example the hypothesis that the truth or falsity of a belief derives from the truth or falsity of the proposition that is believed. This hypothesis can be supported by appeal to the standard analysis of the propositional attitudes. On this analysis, what is shared by, for example, the belief that Jones is in Manhattan and the desire that Jones is in Manhattan is the propositional content *that Jones is in Manhattan*. Now, if the truth of a belief derives from the truth of the proposition believed, we have a natural explanation of the phenomenon whereby the same state of affairs – in this case, Jones's presence in Manhattan – bears equally on the truth of the belief as on the satisfaction of the desire. The explanation would be that the semantic evaluation of the attitudes – their evaluation along the dimensions of truth, or satisfaction, or what have you – is in the first instance an evaluation of their propositional contents. In this way we see how we might support the hypothesis that beliefs have their truth-values derivatively.

The hypothesis that there is a primary bearer of truth-value is the hypothesis that one type of entity bears its truth-value nonderivatively. Which of the three remaining candidates – sentence, proposition, statement – fits this job description?

The Case for the Sentence as the Primary Bearer of Truth-Value

Consider first the sentence. One reason for regarding sentences as the primary truth bearers has to do with a traditional understanding of the aim and scope of logic. Logic is traditionally taken to be (or include) the study of the entailment relation, where a set of sentences of a language *L* entails a sentence *S* of *L* iff *S* is true on every interpretation on which all of the members of are true. Since this talk of ‘truth on an interpretation’ applies to sentences (well-formed formulas), it can be argued that logic itself gives us a motive to treat (atomic) sentences as having their truth nonderivatively (see **Logical Consequence**).

A second consideration in support of the sentence is that certain theories of truth seem to require, or at least to work best with, sentences as the primary bearers of truth. Consider for example those theories on which truth is a relation of correspondence between the facts and the truth bearers (whatever they are). Such theories typically require that candidate truth bearers have a structure that mirrors that of the facts; and it is arguable that sentences are the most apt candidate here (see e.g., Wittgenstein, 1922). So, too, Tarski’s (1944, 1956) semantic theory of truth defines truth in terms of satisfaction, and goes on to characterize satisfaction in a way that makes use of various quasilinguistic distinctions, including that between names and predicates. This, too, appears to call for sentences as the primary bearers of truth.

It is worth noting, though, that neither of the foregoing arguments from the theory of truth is decisive in establishing the sentence as the primary bearer of truth. For example, on at least some conceptions of propositions, propositions can play the roles required by either of the above theories of truth. (For example, the argument from the correspondence theory of truth could be taken to rule out propositions only insofar as these are taken to be unstructured entities: sets of possible worlds, for example.) In addition, there are those theorists who, though rejecting both the sentence and the proposition as the primary bearer of truth, nevertheless endorse Tarski’s semantic theory of truth: one thinks here of Davidson’s (1967) attempt to square Tarski’s theory with a view on which the statement is the primary bearer of truth.

Context and the Question of Truth Bearers

The sentence proposal is not without its share of difficulties. These can be seen when we turn attention from the formal languages typically studied in logic to natural languages. The main problem concerns context sensitivity. A sentence such as (2) is true or false according to who used it, and when.

(2) I am tired

So if sentences are the primary bearers of truth, we face a dilemma. Suppose that sentences which (like [2]) contain a context-sensitive component bear a truth-value. Then such sentences will have to be treated as having a truth-value that changes over time, according to the context of use. But the idea of a truth bearer that changes its truth-value over time is incompatible with the prevalent view (found in Frege, 1918 and elsewhere) that truth bearers have their truth-value timelessly. Suppose then that sentences like (2) do not bear a truth-value. To retain the sentence-as-primary-truth-bearer view, sentences must be found that do bear a truth-value. One natural suggestion comes in the form of Quine’s (1960) ‘eternal sentences’: the truth bearers are those sentences whose truth-value is unaffected by any change of context. But, given other plausible assumptions, the ‘eternal sentence’ view has the revisionary implications, first, that the vast majority of sentences of everyday discourse fail to have a truth-value, and second (and as a result), that most speakers will have a hard time formulating truth-value-bearing sentences.

Presented with this dilemma, the defender of the sentence might think to advert to the distinction between sentence types and tokens. Then the phenomenon of context sensitivity might be taken to establish that it is not sentence types, but rather sentence tokens, that we evaluate for truth. For instance, Mary’s utterance of (2) at noon, and her utterance of (2) at midnight, will present type-identical but token-distinct sentences – in which case we can treat the two sentence tokens as differing in truth-value, while allowing that each token has its truth-value timelessly. (If Mary was tired at midnight of the night of her midnight utterance of [2], then it is **always true** that she was tired then, and her midnight token of [2] is timelessly true.) But it is unclear whether the appeal to the type/token distinction provides a solid defense of the sententialist view of truth bearers. For one thing, it is natural to think that logic deals with sentence types rather than tokens, in which case the sentence token proposal is in tension with the logic-based motivation for the sentence view. For another, it is unclear whether the appeal to the type/token distinction gives us a reason to prefer the sentence

token, as opposed to the statement or the proposition, as the primary bearer of truth. Indeed, it is plausible to suppose that the core lesson of context sensitivity is that it is not sentences themselves (whether construed as types or tokens), but what is expressed by the use of a sentence on a given occasion, that is evaluated for truth.

This understanding of the lesson of context sensitivity has motivated many to look beyond the sentence. Some endorse the proposition, conceived as what is yielded by a semantic evaluation of utterances, as the primary truth bearer. Others, hesitant to endorse propositions given their abstractness and/or the difficulties involved in formulating their individuation conditions, have opted instead for the statement as the primary truth bearer. Since any utterances of e.g., (2) by distinct speakers, as well as any sufficiently temporally distinct utterances of (2) (even by the same speaker), express different statements, treating the statement as the primary truth bearer provides a natural accommodation of context sensitivity. But the relative superiority of the statement to the proposition depends on the controversial claim that statement individuation will be less problematic than, and in any case independent of, proposition individuation.

Ramifications of the Debate about Truth Bearers

As noted at the outset, the dispute over the primary bearer of truth-value bears on various issues in philosophical logic, the philosophy of logic, and the philosophy of language.

Consider for example the class of paradoxes which are often characterized as the 'semantic' paradoxes. The paradigmatic example is the so-called liar paradox, involving a sentence such as the following:

(L) This sentence is false

(For ease of exposition I will speak of sentences, rather than of types or tokens; but the point can be made either way.) If sentences are the primary bearers of truth, we might expect that (L) must be ascribed a truth-value. (This depends on the additional assumption that if sentences are the primary bearers of truth then all sentences must bear a truth-value.) But of course (L) is paradoxical: if it is false then it is true, and if it is true then it is false. Proponents of the sentence-as-primary-vehicle-of-truth view might well take the lesson of the liar to be that we need a logic that permits of more than two truth-values: the third value could be neither true nor false. Alternatively, the lesson of the liar might be that we should reject the claim that it is sentences, as opposed to statements

or propositions, that are the primary bearers of truth: the claim would then be that an utterance of (L) does not express a proposition or make a statement. (Admittedly, both reactions ought to be assessed in terms of the acceptability of their implications, as well as their adequacy as an account of the semantic paradoxes more generally.)

The issue of truth bearers is also relevant to the viability of Russell's theory of descriptions. On the assumption that semantic evaluation is the evaluation of sentences, Russell concluded that sentences containing a definite description – for example, sentences of the form 'The *F* is *G*' – ought to be analyzed as implicitly quantificational, in the manner of 'There is something, *x*, that is *F* and *G*, and anything that is *F* is identical to *x*.' One of the advantages of this analysis is that it can preserve the meaningfulness and truth evaluability of such sentences even if there is no single thing that is *F*. But Strawson (1950) regarded Russell's proposed analysis as plainly artificial: among other things, it requires us to suppose that the grammatical subject of the sentence ('The *F*') is not its logical subject (which, on Russell's analysis, would be the predicates or propositional functions '*x* is *F*' and '*x* is *G*'). On Strawson's diagnosis, Russell was led to such a plainly artificial analysis by his assumption that semantic evaluation is the evaluation of sentences. Strawson rejected this assumption in favor of the view that semantic evaluation is the evaluation of statements; and having done so, he urged that we do not conflate the issue of truth evaluability (a feature of statements) with the issue of meaningfulness (a feature of words and sentences). Thus, on Strawson's analysis, utterances of sentences of the form 'The *F* is *G*' fail to express a statement (and so fail to be truth evaluable) if there is nothing in the relevant context that is uniquely *F*; but even so the sentence uttered would not thereby cease to be meaningful, since meaningfulness is a matter of the rules for the proper use of expressions. In this way we see that issues pertaining to the primary bearer of truth-value have implications for the viability of Russell's theory of descriptions.

The Scope of the Issue

The debate regarding the primary bearers of truth is itself typically presented in connection with the doctrine that truth is a relation (or a property). As it has been formulated here, the issue concerns which entity bears truth-value nonderivatively, and this can seem to be the same as the question regarding which entity nonderivatively possesses the property of truth. One might wonder, then, whether the debate might be dissolved by following so-called minimalist or

deflationary views of truth, according to which truth is not a relation or a property. But as noted in Haack (1978: 83–84), there are questions in the vicinity of the ‘primary bearer’ debate which survive the repudiation of truth as a property or relation. The key issue concerns the application of formal logic to natural language. Consider the familiar *modus ponens* inference rule:

$$\frac{p \quad p \rightarrow q}{q}$$

To apply *modus ponens*, we must find acceptable values for *p* and *q*. But when considering what counts as an acceptable value, we are forced to confront issues of sentential context sensitivity again. To wit: the inference from “I am tired now” and “If I am tired now, I should go to bed now” to “I should go to bed now,” though valid if we keep fixed the time and speaker, equivocates (and so is invalid) if the speaker or time changes from one premise to the next. This has nothing to do with whether one regards truth as a relation; but it does appear to raise most, if not all, of the issues brought up by the primary-bearer debate.

Truth: Theories of in Philosophy

M P Lynch, University of Connecticut, Storrs, CT, USA

Traditional Theories

‘What is truth?’ is a question often deemed to be so perplexing as to be unanswerable. Yet understanding truth is clearly important, as the concept seems to sit at the center of many debates, including those over the nature of knowledge, meaning, and logic. Theories of truth are divided over two basic questions: Does truth have a nature? And, if so, what sort of nature does it have? Traditional theories answer ‘yes’ to the first question and so attempt to give an answer to the second; deflationary theories deny that truth has a nature that needs a deep

explanation. We’ll canvass traditional and deflationary theories in turn.

The oldest theory of truth is arguably the correspondence theory of truth. The basic idea, which may have originated from Aristotle, is that true propositions correspond to the facts. Taken just by itself, this idea is a truism; correspondence theorists add flesh to its bones by spelling out the nature of ‘correspondence’ and ‘facts’ in different ways.

In the early 20th century, for example, Wittgenstein (1922) and Russell (1906) developed a version of the correspondence theory of truth according to which propositions were true in virtue of sharing a common structure with the facts. According to this view, the concepts that compose simple propositions like the *cat is on the mat* exhibit a certain form; and objects

Figure 1 Proposition corresponding to a fact.

(cats, mats) and relations (*being on*) compose basic facts that also exhibit a logical form or configuration. Thus a proposition ‘corresponds’ to a fact just when they share the same form or structure (see **Figure 1**).

Although this sort of view seems to explain the truth of simple propositions about cats and mats well enough, it faces problems with other sorts of facts. Consider the true proposition that there are no unicorns. Is there a negative fact which makes this proposition true? It is unclear whether there are any such facts. In response to these sorts of worries, some philosophers, following Tarski (1943) have attempted to cash out the correspondence intuition in a way that avoids commitment to facts, negative or otherwise, by arguing that propositions are true in virtue of the reference of their parts to objects and properties. The success of this strategy, however, rests on whether a satisfactory account of reference can be given.

Many philosophers also have found fault with the correspondence theory because of worries that it leads to skepticism. According to these philosophers, it is difficult to understand how we could ever “step outside” all language and thought in order to check and see whether our propositions really correspond to the facts. Partly because of these misgivings, philosophers in the 19th century developed the coherence theory of truth (Bradley, 1893). According to the coherence theory, a proposition is true just when it is a member of a coherent system. Thus propositions aren’t true on this view because of their relation to the mind-independent facts but because of their relation to each other. One benefit of this view is that it seems to provide an answer to skepticism. For as long as a proposition ‘hangs together’ with other propositions in the sense defined by the theory, it is true. We don’t have to encounter the naked facts ‘in themselves’ to know what is true and what is false.

Coherence theories, however, have seemed overly permissive to many philosophers. As Russell (1906) famously pointed out, such views imply that any group of propositions – even ones that are obviously false – are true as long as they are mutually coherent. They therefore seem to make too many propositions true.

A third theory of truth was developed by the pragmatist William James (1909) following earlier work by Charles Peirce. According to James’s pragmatist theory, a proposition isn’t true because it copies or coheres with anything. For the pragmatists, propositions are tools, and good tools do good work. Thus, on this theory, a proposition is true just when it is practically justified. A proposition is practically justified in turn when it is useful for achieving our goals over the long run.

The pragmatist theory, however, seems to face an uncomfortable dilemma when asked to explain what makes a proposition useful. If what makes propositions useful is up to us, then again any old claim might turn out to be true. By contrast, if it isn’t up to us, then it seems we must abandon pragmatism. Consider the proposition that my brakes are working in my car. Believing this guides me in making future useful predictions (if I press the brakes the car will stop). But presumably it is only useful for me to believe that the brakes are working if it is really true that they *are* working. But this is not something the pragmatist can say, since we just invoked truth to explain usefulness instead of the other way around.

Deflationary Theories

Deflationary theories of truth are so called because they deflate the pretensions of traditional theories which attempt to define the underlying nature of truth. Deflationists take the fundamental fact about truth to be

(T) The proposition that *p* is true if and only if *p*.

The basic idea is that this schematic principle (more or less, depending on the variety of deflationism involved) explains all there is to explain about truth.

Most deflationary views have two aspects. The first and arguably most central is the metaphysical thesis already mentioned that truth has no underlying nature. This is often put by saying that there is no property, or at least no substantive property, shared by all and only true propositions. Deflationists typically argue for this claim by trying to show that, contra the tradition, we needn’t appeal to anything other than (T) to explain truth’s involvement in

knowledge, meaning and logic. The second aspect of any deflationary theory is a semantic thesis about the role, if any, the word “true” plays in our language.

The simplest form of deflationism is the redundancy theory of truth, and stems from work by Frege and possibly Ramsey (1927). On this account, we need no separate semantic explanation of truth, for ‘it is true that p’ is just another way to say ‘p.’ To say that it is true that roses are red, for example, is really just to say in different words that roses are red. Thus, we only *appear* to ascribe a property to a sentence or proposition when we say that it is true; we are in reality ascribing nothing as ascriptions of truth are simply superfluous or redundant; they add nothing to the content of what has already been said.

The redundancy theory faces two crippling problems. First, there are counterexamples to its central claim. Consider, to take just one example, the proposition that

(S) Everything that Socrates said is true.

Clearly, the claim that *Everything Socrates said is true* is not equivalent to the fragment that *Everything Socrates said*. Accordingly, all ascriptions of truth are not redundant as the theory demands.

The second problem for the redundancy theory and other early forms of deflationism concerns whether and how we generalize over schema (T) in order to offer a suitable definition of truth. Redundancy theorists had a problem offering such a definition because using ordinary objectual quantification, it is hard to see how one could convert (T) into a suitable explicit definition. The natural suggestion ‘For any proposition p, the proposition that p is true if and only if p’ isn’t, strictly speaking, well formed, because ‘p’ is being used as two different types of variables. Where it appears as a conjunct by itself, on the right-hand side of (T), it is used as a proposition; but, on the left-hand side, it has the character of a name being completed by a predicate.

Contemporary deflationists have made numerous suggestions as to how to deal with these two problems. Like the redundancy theory, the minimal theory (Horwich, 1998) holds that (T) is the most fundamental fact about truth. But, unlike the redundancy theorist, minimalists believe that ‘the proposition that snow is white is true’ and ‘snow is white’ are only necessarily equivalent, not synonymous. Moreover, they can acknowledge that truth is property. It is just not a substantive or natural property that needs any sort of *metaphysical* explanation. Minimalists also reject the need for an explicit definition of truth. They argue that truth is instead

implicitly defined by all the instances of (T), and that our grasp of the concept consists in our disposition to accept these instances. Finally, following Quine, minimalists hold that our concept of truth does serve an important purpose. Without it, rather than asserting (S) above, we would face the impossible task of expressing an indefinitely long conjunction, namely:

If Socrates said roses are red, then roses are red,
if Socrates said violets are blue then violets are blue ...

But with (T) in hand, we may say instead that for every object x, such that x = what Socrates said, then x is true. The minimalist concludes that the sole function of the concept of truth is to allow us to generalize over open-ended strings of claims like this.

One issue dividing contemporary deflationists concerns the proper bearers of truth. Disquotationalists (e.g., Quine, 1990) are skeptical about the existence of propositions and take sentences or even utterances, to bear truth. Hence, they take as their central principle not (T) but the disquotation schema

(D): “S” is true if and only if s.

So-called pure disquotationalists, following Field (2001), go even farther. They take the concept of truth to apply only to sentences that we understand. Other philosophers have objected that this is too stringent, as it seems that we can apply the concept to sentences we can’t understand, as when I say that most of what Socrates said was true, even though I don’t understand ancient Greek.

A pressing problem for any form of deflationism, first raised by Dummett (1978), is how to account for the normative role truth plays in thought and language. It is a truism that in asserting propositions and forming beliefs, we aim at the truth. That is:

(TN) Other things being equal, we ought to believe what is true.

But it is difficult to see how (TN), which deals with what ought to be the case, can be deduced from (T), which deals only with what is the case. Deflationists typically reply that (TN) is simply another example of the generalizing function of truth. That is, (TN) is simply short for a long conjunction of individual norms of the form:

(B) Other things being equal, we ought to believe p when p.

And (TN) can be deduced from (T) along with (B). The issue remains unclear, however. For the deflationist now faces the difficult task of explaining why we

should accept all instances of (B) without invoking the fact she set out to explain: that it is good to believe what is true, that is, (T).

Alternative Theories

Recently, several different theories of truth have sprung up as alternatives to both traditional and deflationary views of truth. The identity theory (Dodd, 2000) holds that true propositions do not correspond to the facts but are rather strictly identical to facts. Primitivism (Davidson, 1990) holds that truth is a primitive, indefinable property that we cannot explain in simpler terms that don't already presuppose it. Finally, alethic pluralism (Wright, 1992; Lynch, 2004) holds that truth may come in more than one form, in that propositions in different domains might be true in different ways. Thus, propositions about the physical world around us may be true by corresponding to the facts, whereas those about morality may be true in virtue of their coherence with other propositions. Thus, the pluralist rejects traditional theories in so far as they try to say that all propositions are true in a single way. But, unlike the deflationist, they hold that there are more facts about truth than (T). The main problem with such theories, however, is to spell out exactly what is in common between all these ways of being true; that is, to say what makes them all 'ways of being true.'

20th-Century Linguistics: Overview of Trends

G Graffi, University of Verona, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Two theoretical trends can be considered as hallmarks of 20th-century linguistics: structural linguistics and generative grammar. They almost equally

divide this epoch: structural linguistics (or, shortly, structuralism) flourished between the 1910s and the 1950s, generative grammar from the 1950s. Structuralism was not a unitary theory, but rather a galaxy of schools sharing some principles; furthermore, some important differences distinguish European structuralist schools from the American one. Generative grammar, instead, originated as a unitary theory,

which subsequently divided into different schools and which stimulated several alternatives from scholars not accepting it.

Both structural linguistics and generative grammar also had an impact outside linguistics: between the 1950s and 1970s (especially in France), the former became the model for all humanities, hence a 'structural' anthropology, a 'structural' sociology, etc., were developed. Generative grammar, in its turn, was seen as one of the initial steps of the so-called cognitive revolution. Neither of these extensions was free of problems: in many cases, concepts of structural linguistics were applied to other fields with some illegitimate modifications, and the debate on what 'cognitive' really means has not yet come to a solution. All this, however, does not lessen the outstanding role of both structuralism and generative grammar within 20th-century linguistics and within 20th-century thought in general. This article will therefore focus almost exclusively on these two theoretical trends: even sociolinguistics will be dealt with rather as an alternative to generative grammar rather than in its applied aspects (language policy, etc.). Also other fields, such as language teaching, experimental phonetics, and so on, will not be presented in this overview: this does not mean that they have not reached important results during the 20th century.

20th-Century Linguistics vs. 19th-Century Linguistics: Continuities and Breakthroughs

It is a widely held opinion that the 19th century has been 'the century of comparative and historical linguistics' and the 20th century that of 'general' or 'theoretical' linguistics. Such an opinion is certainly not ungrounded, but it needs some qualifications. Indeed, historical linguistics in the modern sense originated in the 19th century and experienced an astonishingly fast development: in the course of about 80 years, the whole structure of historical-comparative grammar of Indo-European languages reached its final form. Later discoveries (e.g., of languages like Hittite or Mycenaean Greek) added some new data, but the overall architecture built by the Neogrammarians nevertheless remained valid, and it is still today the frame of reference for any historical linguist working in the domain of comparative grammar of Indo-European languages. However, historical-comparative grammar was not the only subject investigated by 19th-century linguists; as a matter of fact, many of them dealt with topics that one would certainly label, today, 'general linguistics.' This phrase may refer to somewhat different research perspectives, as, e.g., (1) speculation on language

in general, hence also on language change (and investigation of the principles of historical linguistics plainly enters into this kind of research), and (2) all kind of linguistics that is not historical ('synchronic,' or 'panchronic' in Saussure's terms). Both kinds of general linguistics were practiced during the 19th century. W. von Humboldt (1767–1835) was not an isolated exception: his speculations on the nature of language and his typological classification of languages were developed by several of his followers, such as Heymann Steinthal (1823–1899), Georg von der Gabelentz (1840–1893), and Franz Misteli (1841–1903). But also the first generations of comparative linguists had the study of language in general as their first goal. For example, Franz Bopp (1791–1867) reconstructed Proto-Indo-European verbal forms according to a scheme of verb phrase, which is heavily influenced from Port-Royal views. Even August Schleicher's (1821–1868) views about language and language change belong to 'general linguistics' in the former of the senses alluded to earlier. The debate of the 1880s, about the 'sound laws' (*Lautgesetze*), possibly marks the highest point of this kind of general linguistics: shortly after conclusion of such debate, it gradually became less and less important. A 'paradigm' in the Kuhnian sense has developed: the majority of scholars consider only a given set of problems as 'scientific,' namely those of a historical kind. This paradigm is general labeled as the 'Neogrammarian' one: but it cannot be forgotten that many of the Neogrammarians also dealt with topics of general linguistics in both senses quoted earlier. The often labeled 'Neogrammarian Bible,' namely Hermann Paul's (1846–1921) *Prinzipien der Sprachgeschichte* (I ed. 1880; V and last ed. 1920), deals with topics both of historical linguistics and of general linguistics. For example, Paul defined some oppositions that seem to foreshadow some Saussurean dichotomies (see next section) – that of 'descriptive grammar' vs. 'historical grammar' (which could be held to correspond to that between synchronic and diachronic linguistics), or that of 'individual linguistic activity' vs. 'linguistic usage,' which could be considered analogous to that of *parole* vs. *langue*. Similar distinctions were also introduced by Gabelentz in his *Sprachwissenschaft* (I ed. 1891; II ed. 1901), where three meanings of the term *language* (*Sprache*) are distinguished: (a) 'discourse' (*Rede*); (b) 'a totality of expressive means for any thought'; and (c) 'linguistic capacity' (*Sprachvermögen*), i.e., "a faculty innate to all peoples of expressing thought by means of language." Sense (a) could be made to correspond to Saussure's *parole*, sense (b) to *langue*, and sense (c) to *faculté de langage*. Even if it is quite probable that Saussure knew both Paul's and

Gabelentz's work, such correspondences are more seeming than real, as will be seen in the next section. The fact cannot be overlooked, however, that such matters typically belong to general linguistics. As can be seen from their life dates, neither Gabelentz nor Paul were much older than Ferdinand de Saussure (1857–1913): why, then, are they normally presented in histories of 19th-century linguistics, whereas Saussure is considered as the 'father' of 20th-century linguistics? This is mainly due to the fact that Saussure and his followers dealt with more or less the same stuff, but in a different perspective. Summarizing so far, one could say that topics in general linguistics show a continuity between the 19th and 20th centuries, but the way of looking at them shows a definite breakthrough.

Ferdinand de Saussure

As is well known, Saussure's *Cours de linguistique générale* (Saussure, 1922) was not directly written by him, but it was compiled by two former students, Charles Bally (1865–1947) and Albert Sechehaye (1870–1946), on the basis of the notes from class lectures given by Saussure in the academic years 1906–7, 1908–9, and 1910–11 at the University of Geneva. It is perhaps lesser known that neither Bally nor Sechehaye attended any of these lectures: they simply reworked and systematized the notes that others had passed to them. As a result, their reconstruction is often considered not quite faithful to the authentic Saussurean thought, especially after detailed studies of the handwritten notes by Godel (1957) and their edition by Engler (1967–74). Tullio De Mauro's very detailed and insightful commentary on the *Cours* (published since 1972 together with Saussure's original text) stresses many points of Saussure's original thinking that were more or less modified by the editors. Today the exact knowledge of Saussure's ideas cannot be gained without the support of De Mauro's commentary and/or the attentive reading of Engler's edition. Nevertheless, because only the Bally–Sechehaye edition was available until the 1960s, this text actually influenced the immediately subsequent linguists. Hence, reference will be made in what follows almost exclusively to the Bally–Sechehaye edition.

Saussure's linguistic views are standardly epitomized by his so-called dichotomies: (1) *langue* vs. *parole*; (2) synchrony vs. diachrony; (3) signifier vs. signified (*signifiant* ~ *signifié*); and (4) associative vs. syntagmatic relations. (1) opposes the social aspect of language, the code shared by a speaking community (*langue*), to the individual speech act (*parole*); (2) opposes the state of a language at a given moment of its history to

its change during the time; (3) defines the 'two sides of the linguistic sign,' namely the 'acoustic image' and the 'concept'; and (4) opposes the relation between elements in succession, such as *teach* + *ing* in *teaching*, to that between elements alternative to each other: e.g., *teaching* as alternative to *learning*, or *studying*, etc. All these dichotomies were surely attested in 19th-century linguistics: that of the social vs. the individual aspect of language was already sketched among others by Paul and Gabelentz (see previous section; it must be added that Saussure also hinted at the notion of *faculté de langage*, language faculty, which shows analogies with Gabelentz's *Sprachvermögen*); the synchrony/diachrony opposition could have a foreshadowing in Paul's distinction between 'descriptive grammar' and 'historical grammar'; the idea that the linguistic sign is two sided, in the sense that the meaning is not external, but internal to it, could be traced back even to the Stoics; and also the existence of two kind of relations in language could already be found, e.g., in some of Paul's pages. Two features, however, strongly differentiate Saussure from his predecessors: (1) a systemic approach, and (2) a strong tendency to define the basic concepts of linguistics without anchoring them to other disciplines, such as sociology, psychology, etc. Saussure's key notion is that of language (*langue*) as a 'system of signs,' each of which has no intrinsic value, but whose value is determined solely by their relationships with the other members of the system ("*dans la langue, il n'y a que des différences*"; Saussure, 1922: 166; original emphasis). This sign system is the code shared by all members of a linguistic community, and its only root lies in this common sharing, because linguistic signs do not have any intrinsic value. Linguistics is a part of a more general science called semiology, namely "*une science qui étudie la vie des signes au sein de la vie sociale*" (Saussure, 1922: 33; original emphasis). *Langue* is therefore a social notion because of its character of semiological code: *parole* is the use by the individual of this general code. Because linguistic signs have no foundation in external reality, but are purely differential entities, they can change across the time; this is the reason for the distinction between synchrony and diachrony. In Saussure's view, however, system exists only in synchrony, at a given moment of time; diachrony does not concern systems, but only isolated elements. A linguistic change is therefore isolated and fortuitous; only when a given sign is changed, a new system is formed, because the relations between signs are different from earlier. Finally, associative and syntagmatic relations are synchronic, because they are essentially systematic.

Saussure's view of language paved the way to what was later called structural linguistics. Even if neither 'structure' nor 'structural' (but just *système*)

occur throughout Saussure's text in a technical sense, the systemic approach to language and the definition of linguistic notions and categories on a purely linguistic basis (i.e., without reference to psychological categories, and so on) became the starting points of structural linguistics.

Saussurean Trends in Europe

Geneva School

The editors of Saussure's *Cours*, namely Bally and Sechehaye, were only weakly influenced by the systemic and autonomous approach to language developed in that book. This may seem paradoxical, but it has to be kept in mind that both Bally and Sechehaye had completed their linguistic formation before Saussure's lectures in general linguistics. Among Saussurean notions, Bally especially deepened the *langue/parole* opposition. According to him, *langue* preexists *parole* from a *static* point of view. This relationship, however, is reversed from the *genetic* point of view, because *parole* preceded *langue* in the genesis of language (see, e.g., Bally, 1965). Sechehaye was concerned with problems of general linguistics and its relationships with psychology and sociology since his first book (Sechehaye, 1908); in subsequent years he analyzed some fundamental problems of syntax, such as the notion of sentence. These analyses are insightful, but essentially extraneous to the structuralist trend. A stronger structuralist approach characterizes the work of Bally's pupil, Henri Frei (1899–1980); he revisited Saussure's ideas on syntagmatic and paradigmatic relationships, on the one hand, while on the other hand he confronted other descriptions of syntactic structure, mainly those of Bloomfield and of the American structuralist school (see later discussion).

Prague School

The so-called Prague School was formed by a group of linguists belonging to the 'Prague linguistic circle,' founded in 1926 by the Czech anglicist Vilém Mathesius (1882–1945). Members of this circle were, among others, the Russian scholars Serge Karcevskij (1884–1955), Roman Jakobson (1896–1982), and Nikolaj S. Trubeckoj (1890–1938). Prague School dealt with a variety of topics, from English syntax to literary criticism; however, it is especially known for its critical development of Saussurean notions expounded in the theses presented to the first International Congress of Linguists ('Prague Theses,' 1928) and for the contributions of some of its members to phonology (especially Trubeckoj and Jakobson).

Among the most influential statements contained in Prague Theses, the following two can be quoted: (1) language is a functional system, whose goal is communication; and (2) the synchrony/diachrony dichotomy is not so neat as Saussure presented it: on the one hand, no linguistic state can be considered as totally independent from evolution and change; on the other, phonetic change is not blind and unsystematic as Saussure assumed, but it must be considered in the framework of the sound system that underpins it.

The most important Prague work on phonology is surely Trubeckoj's posthumous and unfinished *Principles of phonology* (Trubeckoj, 1939). Phonology was defined by Trubeckoj as "the science of sounds of *langue*," whereas phonetics is "the science of sounds of *parole*." The key notion of phonology is phoneme. Phoneme (the phonological unit) is opposed to sound (the phonetic one): the former is abstract, the latter is concrete and 'realizes' the phoneme. When two sounds occur in exactly the same positions and cannot be changed without a change in the meaning of the words, they are different realizations of the same phoneme ('rule 2' of Trubeckoj, 1939): e.g., English [t], [p], and [k] realize three different phonemes, /t/, /p/, and /k/ because they distinguish, among others, the three words *tin*, *pin*, and *kin*. Two sounds may be different and nevertheless belong to the same phoneme: for example, English [t], [p], and [k] in the preceding examples are produced with an extra puff of air, but this puff of air does not occur, e.g., in *spin*. These two sounds do not distinguish any meaning: they are variants of the same phoneme. Phoneme inventories differ from language to language: sounds that realize the same phoneme in a language may be realizations of different phonemes in other languages. For example, aspirated stops are variants of the same phoneme in English, but they realize a phoneme of its own in Hindi.

Since the late 1940s, Jakobson remarked that phonemes are not the 'smallest distinctive units,' but they are actually constituted by even smaller entities, the distinctive features. For example, /d/ differs from /n/ (cf. *dine* vs. *nine*) because of the feature 'nasality'; and it differs from /t/ (cf. *do* vs. *to*) because of the feature 'tensedness.' During the 1950s, Jakobson, together with Morris Halle (b. 1923) further worked out his theory: any phoneme of any language is analyzed as containing or not containing a given feature from a universally fixed set of 12 (later 14) features, whose values are + or –; (binary value, hence the label of binarism given to the theory). For example, English /t/ would have the following features: [-vocalic], [+consonantal], [-compact], [-grave], [-nasal], [+tense], [-continuous] (for the meaning of these

terms, see Jakobson and Halle, 1956). Both consonants and vowels are defined on the basis of the same features, and all languages have only this inventory of features at their disposal (but some languages exploit only some of them). Jakobson's binarism was adopted (with some modifications) also by generative phonology (see discussion under Generative Phonology Section).

Copenhagen School

The most well-known linguists of the 'Copenhagen school' are Viggo Brøndal (1887–1942) and Louis Hjelmslev (1899–1965). Both scholars vigorously maintained the structuralist point of view and their Saussurean heritage. Nevertheless, their approach to language in general and to syntax in particular shows many differences; whereas Brøndal considered *language* to be based on logic, Hjelmslev's program was to give *linguistics* a logical basis, in the sense of the 'logic of science,' which was being developed in the 1930s by the neopositivistic philosophers.

In his most important book, Hjelmslev (1943) aimed at constructing a deductive theory of language that he dubbed *glossematics*. Such a theory should be based on purely linguistic notions ('immanent linguistics') and should follow rigorous methodological standards (it has to be "self-consistent, exhaustive and as simple as possible"). Hjelmslev assigned special importance to Saussure's statement that "language (*langue*) is form, not substance." He therefore distinguished form and substance both on the phonological and on the syntactico-semantic level (expression plane and content plane respectively, in his terms). On the expression plane, a continuous stretch of sound can be differently articulated, according to the different phonemic inventories: e.g., where English distinguishes three nasal phonemes (/m/, /n/ and /ŋ/), Italian only distinguishes two (/m/ and /n/). On the content plane, the same continuum can be differently subdivided: e.g., English divides the color spectrum from green to brown in four sections (*green, blue, gray, brown*), whereas Welsh divides it in three (*gwynedd, glas, llwyd*). Both planes are analyzable, according to Hjelmslev, into smallest units, which are limited in number, that he called *figuræ*: expression *figuræ* are phonemes, content *figuræ* are semantic units from which larger semantic units can be constructed (e.g., *man* would be formed by the content *figuræ* 'human,' 'male,' 'adult'). Content *figuræ* and expression *figuræ* are not in one-to-one correspondence: this is the reason why two planes are postulated (otherwise, such a postulation would be superfluous and the theory would violate the simplicity requirement). Any structure that has an expression

plane and a content plane is named by Hjelmslev a *semiotic*, whereas structures with one plane only are 'symbolic systems.' Each plane can in its turn be constituted by a *semiotic*, and so on.

Structural Linguistics in France: Benveniste, Martinet

Émile Benveniste (1902–1976) combined his experience in the field of historical-comparative grammar of Indo-European languages with a particular skillfulness in the analysis of linguistic facts. He was surely well acquainted with the patterns of investigation worked out by European and American structuralism, but he resorted to them only to a limited extent. Somewhat paradoxically, this allowed him to sketch some analytical proposals that are sometimes superior to those of the structuralists. Among such proposals (see Benveniste, 1966), the most well known are his remarks on Saussure's notion of arbitrariness of linguistic sign and those concerning the definition and classification of grammatical persons and of pronouns, which parallel the investigations about performative utterances developed by Austin more or less during the same years (cf. Pragmatics section).

André Martinet (1908–1999) was in the 1930s, a foreign member of Prague linguistic circle; he consistently developed that 'functional view' of language explicitly stressed by the Prague theses (see Prague School section). Natural languages, in Martinet's view, have three features in common: (a) their communicative function, (b) their use of vocal utterances (i.e., natural language is essentially and primarily a vocal phenomenon, and only derivatively a written one), and (c) the double articulation, i.e., a first articulation into significant units ('monemes,' a term borrowed from Frei, but with a somewhat different sense, to replace 'morpheme'), which are in their turn articulated into distinctive units ('phonemes'). One of the most interesting instantiations of Martinet's functionalism is his investigations of diachronic phonology (cf. Martinet, 1955); the 'economy' of sound changes is the effect of the balance of two opposed tendencies, the 'minimal effort' (which tends to lessen sound differences) and 'communicative efficiency' (which tends to multiply them).

Other European Scholars (Guillaume, Tesnière, London School)

The scholars presented in this section, however, certainly influenced by Saussurean thought and hence ascribable to the structuralist trend, nevertheless remained somewhat aside from the debate that developed about the basic tenets of structural

linguistics, especially between the two World Wars. This fact occurred also because the most significant works of some of them (e.g., Guillaume and Tesnière) were only posthumously published (see Guillaume, 1971–1990; Tesnière, 1966).

The writings of the French linguist Gustave Guillaume (1883–1960) are often difficult to read and interpret, especially because of the dark philosophical style that shows many influences. That by Henri Bergson (1859–1941) is especially significant in Guillaume's analysis of concept of 'time' (which he does not clearly distinguish from that of 'tense'). Among the several topics dealt with by Guillaume, one can quote his opposition between what is a formal expression in language ('psychosemiotics') and what is expressed by it ('psychosystematics'); only what has a morphophonological representation of its own can be called semiotic. Guillaume also proposed to replace Saussure's terminological pair *langue/parole* with *langue/discours* (speech). Speech necessarily presupposes language: their relationship can be expressed in terms of the pair 'power' (language) vs. 'effect' (speech).

Lucien Tesnière's (1893–1954) work is especially important for its contribution to syntax. The seminal notion of Tesnière's syntax was that of valency. Tesnière compared the verb to "a kind of hooked atom" that can exert its power of attraction on a smaller or bigger number of 'participant roles' (*actants*). Besides participant roles, the sentence may also contain some 'circumstantial roles' (*circonstants*), which express the conditions of place, time, manner, etc., in which the process described by the verb takes place. Participant roles are obligatory; circumstantial roles are optional. The number of participant roles varies according to the verb class to which the verb belongs, so we have several verb classes according to their 'valency sets.' If Guillaume's linguistic thought did not exert any special influence on subsequent scholars, Tesnière's lies at the origin of several of the most important developments in syntax during the second half of 20th century (cf. Functionalist Schools section).

Among the linguists of the 'London school,' Daniel Jones (1881–1967) and John R. Firth (1890–1960) especially have to be cited. Jones was a phonetician deeply involved in practical questions (such as, for example, the assessment of the principles of phonetic transcription), but he also faced theoretical questions, such as the definition of phoneme. In contrast with the more abstract view held by Trubeckoj (cf. Prague School section), who defined phoneme on an exclusively linguistic basis, Jones opted for a 'physical' definition of phoneme as "family of sounds related in character no member of which occurs in the same phonetic context of any other member." Jones

also rejected Trubeckoj's sharp opposition between phonetics and phonology.

Firth's view of language is characterized by the key role it assigned to the notion of context. He defined 'meaning' as 'function in context': not only words and sentences, but even phonetic units have meaning. Firth's contextual approach was especially fruitful in phonology. In his view, phonology cannot be limited to the segmentation and classification of sounds and phonemes ('paradigmatic units'), but must take into account also prosodic, 'syntagmatic' units such as the syllable (hence the name of 'prosodic phonology' given to Firth's theory). It is therefore necessary to study syllabic structure in terms of general sound classes, such as C(onsonant) and V(owel), and of their respective positions. Firth also maintained that grammar (i.e., syntax and morphology) and phonology are interdependent, anticipating in this way positions that will be later held in generative phonology (cf. Generative Phonology section).

Among Firth's students, one may cite R. H. Robins (1921–2000), especially for his historical researches on classical and medieval linguistics, and M. A. K. Halliday (b. 1925), whose 'Systemic Functional Grammar' (see Functionalist Schools section), worked out since the 1960s in successively revised versions, had several important applications in many fields, as artificial intelligence, discourse analysis, or language education.

American Linguistics from 1920s through 1960s

Sapir and His Heritage

American linguistics began to show peculiar features, different from those of European linguistics, from the beginning of 20th century. At that time, mainly because of the influence of the anthropologist Franz Boas (1859–1942), American linguists oriented a lot of their research to the study of Amerindian languages. Because such languages were devoid of written tradition, these scholars were automatically led to adopt a synchronic point of view. Furthermore, given the difficulty of applying the notions of Western grammar to such languages, attempts had to be made at describing them in purely formal ways: this led to the development of 'distributional' and 'classificatory' methods, i.e., based on the observation of pure occurrences of forms.

Edward Sapir (1884–1939) was himself an anthropologist and a linguist at the same time and devoted much of his research to Amerindian languages. His theoretical ideas are expressed in his book *Language* (Sapir, 1921), and in several papers posthumously

collected (Sapir, 1949). According to Sapir, language is an ‘overlaid function’ from a physiological point of view, because it is a psychological and symbolic phenomenon. Hence, a purely physiological view of speech sounds, as was typical of late 19th-century experimental phonetics, is untenable: e.g., English *wh*-sound as in *when*, *where*, etc., is physiologically identical with the sound produced blowing out a candle, but the two sounds are essentially different, because only the linguistic *wh*- is ‘placed’ in a system that is composed “of a definitely limited number of sounds.” In this way, Sapir arrived at a psychological conception of phonemes and variants.

Sapir’s classification of grammatical concepts, on which his new approach to language typology is based, also deserves special mention. He classified them into two main groups: concepts that express ‘material content’ and ‘relational’ concepts. Each of both groups is further subdivided into two groups: so one obtains ‘basic concepts’ (1a), ‘derivational concepts’ (1b), ‘concrete relational concepts’ (2a), and ‘pure relational concepts’ (2b). Concepts (1a) and (1b) are mainly semantically (or ontologically) based; they are ‘objects,’ ‘actions,’ ‘qualities’ (1a) and their derivations (1b). Gender and number belong to the group (2a), whereas grammatical relations (subject, object, attribute, etc.) belong to pure relational concepts (2b). The possible combinations of the four groups of concepts brings about Sapir’s classification of languages into four ‘conceptual types.’ Type (A) languages only contain concepts (1a) and (2b); those of type (B), concepts (1a), (1b) and (2b); those of type (C), concepts (1a), (2a) and (2b); those of type (D), all four kinds of concepts.

Among Sapir’s followers the important contribution of Morris Swadesh (1909–1967) to phonemics (a term that corresponds to the European ‘phonology’) is to be noted. The most well-known heritage of Sapir’s thought is, however, the so-called Sapir–Whorf hypothesis, so called after his name and that of his follower, the nonprofessional linguist Benjamin L. Whorf (1897–1941). According to the theory, our vision of the world is heavily conditioned by our language. This hypothesis is today rejected, especially by those linguists, as generative grammarians, who maintain that cross-linguistic differences are actually more apparent than real. On the other hand, generative grammarians have often reevaluated Sapir’s work against Bloomfield’s, because of its psycholinguistic (or mentalistic) approach strongly avoided by the latter.

Bloomfield

Leonard Bloomfield’s (1887–1949) behavioristic approach (see especially chap. 2 of Bloomfield, 1933)

essentially consists of describing language as a chain of stimuli and responses (S-r-s-R): a speech event takes place when a nonlinguistic stimulus (S; e.g., hunger) produces a linguistic response (r) in the speaker (*give me something to eat!*) and such a response in its turn induces a linguistic stimulus (s) in the hearer, which has as a consequence the hearer’s nonlinguistic response (R; e.g., providing food).

Bloomfield’s major contribution to linguistics certainly does not lie in this crudely mechanistic view of language function, but instead in the working out of some analytical tools, particularly in the domains of morphology and syntax. The most influential of such tools is the so-called Immediate Constituent (IC) Analysis (see Bloomfield, 1933: chap. 13). In the classical example *Poor John ran away*, the immediate constituents are *Poor John* and *ran away*. The analysis goes on by partitioning *poor John* into *poor* and *John*, and *ran away* into *ran* and *away*. Furthermore, *away* is also analyzed into *a-* and *way*: the principle of immediate constituent analysis applies to morphology exactly in the same way as to syntax. IC analysis was subsequently deepened and formalized, not only by ‘post-Bloomfieldian’ linguists, but also within generative grammar.

Post-Bloomfieldian Structuralism

Linguists most directly influenced by Bloomfield’s thought and analytical techniques especially developed the operational and distributional features of his conception of language. One of the most typical examples of this methodological trend was the so-called prohibition of mixing levels: phonological analysis must precede grammatical analysis and must not assume any part of the latter.

Among post-Bloomfieldian scholars, the following can be quoted, according to the different linguistic domains: concerning phonology, William F. Twaddell (1906–1982), Bernard Bloch (1907–1965), and George L. Trager (1906–1992); concerning morphology and syntax, besides Bloch and Trager, Eugene Nida (b. 1914); a very important intervention in the domain of IC-analysis is due to Rulon S. Wells (b. 1919); possibly, the leader of the group can be considered Charles F. Hockett (1916–2000), who dealt with all such different fields and also worked on theoretical problems, especially in polemics with generative grammar. The most original and influential among American structuralists is, however, Zellig S. Harris (1909–1992): in the 1940s, he was engaged in the deepening and the formalization of Bloomfield’s analytical techniques (see especially Harris, 1951); in the early 1950s, he worked out the notion of transformation. In Harris’s framework, a

transformation is seen as an equivalence relation between two different sentence-forms: e.g., *Casals play the cello* and *The cello is played by Casals*, or *he met us* and *his meeting us* are ‘transforms’ of each other. The notion of transformation (with important modifications) was to become a cornerstone of generative grammar, especially in its first phases (see later discussion).

Tagmemics and Stratificational Grammar

Tagmemics is the name given to the linguistic theory worked out by Kenneth L. Pike (1912–2000) and his associates and students. It combines both Bloomfield’s and Sapir’s insights, but it trespasses the boundaries of American structuralism in many respects. The Bloomfieldian side of tagmemics lies in its analytical techniques, which resume, deepen, and modify Bloomfield’s. On the other hand, Pike’s approach to language is decidedly and explicitly Sapirean: language is seen as a cultural phenomenon, strictly tied to other cultural manifestations of human life.

Stratificational grammar was developed by Sydney M. Lamb (b. 1929) beginning in the late 1950s. It combines a post-Bloomfieldian approach with some European perspectives, mainly Hjelmslev’s glossematics and Halliday’s Systemic Functional Grammar. The number of assumed strata varies from two to six, according to the different versions of the theory. Mostly, four strata are assumed: semotactics, lexotactics, morphotactics, and phonotactics. Stratificational grammar aims at giving an account of all kind of linguistic processes, i.e., concerning both competence and performance (see later discussion): it shows, therefore, a ‘cognitive’ approach that sharply differentiates it from classical post-Bloomfieldian theories and makes it closer to generative grammar, although it is very distant from this latter theory both in the assumed principles and on many technical aspects.

The Beginnings of Typological Linguistics

Language typology was an important field in 19th-century linguistics, but was rather overlooked during the first half of 20th century, because Sapir’s work on the topic remained an isolated exception. Things began to radically change in the 1960s, especially stimulated by the work of Joseph H. Greenberg (1915–2001). In Greenberg’s perspective (see Greenberg, 1966), a close link is assumed between typology on the one hand and universals on the other. Language universals are no longer exclusively conceived as features that every language *must* possess: to such universals, named by Greenberg ‘unrestricted’ universals, also implicational universals and statistical correlations have to be added. The most well

known instances of implicational universals concern the linear ordering of elements. Greenberg assumed as the bases of his language classification three possible choices: (1) whether a language has prepositions or postpositions (‘prepositional’ vs. ‘postpositional’ languages). (2) The position of the verb (V) with respect to the subject (S) and to the object (O). Of the six theoretically possible positions, only three normally occur: VSO, SVO, and SOV. (3) The order of the adjective with respect to the noun it modifies: A (= AN) vs. N (= NA). Such choices are systematically correlated with each other in an implicational way: this implication can be exceptionless or only statistically significant. An instance of the first case is the statement that if a language shows VSO order, it is *always* prepositional (Greenberg’s Universal 3). On the other hand, Greenberg’s universal 4 is an example of ‘statistical correlation’: if a language has a normal SOV order, it is postpositional “with overwhelmingly more than chance frequency.” Greenberg’s insights caused a tremendous development of typological studies, as will be seen in the Typological Linguistics section.

The Birth and Rise of Generative Grammar

The Origins of Generative Grammar

Generative Grammar (GG) is the label for the linguistic theory developed by the American scholar Noam Chomsky (b. 1928) and his followers; a GG, in Chomsky’s own word, is “a system of rules that in some explicit and well-defined way assigns structural descriptions to sentences” (Chomsky, 1965: 8). Chomsky was a student of Harris (cf. previous section), but he early adopted a ‘mentalistic’ approach to the problems of language and knowledge, highly polemical against the behavioristic one, typical of Bloomfieldian and post-Bloomfieldian linguistics.

The first systematic version of Chomsky’s theory appeared in print in a booklet called *Syntactic Structures* (Chomsky, 1957), which was partly an abstract of a much more voluminous work written in the years 1955–56 and published only 20 years later, with some modifications. The main features shown in this book with respect to the tradition of American structural linguistics were the following ones: (1) the goal of linguistic description is no more seen in the analysis of a given corpus, but in the accounting for the intuitions of the native speaker of a given language (well-formedness of sentences, synonymy, etc.). (2) A sharp distinction is traced between linguistic theory on the one hand and grammar on the other. (3) IC-analysis typical of American structuralism (see previous discussion) is formalized in a system of rules called

Phrase-structure (PS) grammar. (4) PS-grammar is shown not able to adequately account for all sentences of any natural language. For example, it cannot account for the intuitive relation that any English speaker recognizes between two sentences such as *Mary gave a book to John* and *John was given a book by Mary*, or between the latter and *Who was given a book by Mary?* To account for such kind of relations, it is necessary to postulate a further level of rules, called transformations. This notion was borrowed from Harris, but it is rather differently conceived. Whereas, for Harris, it is a relation between sentences, for Chomsky it is a relation between structures. This means that the input of a transformation is a sentence in Harris' framework, whereas in Chomsky's one it is an abstract structure often rather remote from the actual sentence that it underlies. The importance given to the notion of transformation in the early phase of GG had the effect that Chomsky's theory was initially known as transformational grammar rather than as generative grammar (actually, the use of the latter label was rather unsystematic at that time).

The Standard Theory

In the decade 1955–1965, the model of grammar described in the previous section was modified by Chomsky himself and by some of his early associates, such as Charles J. Fillmore (b. 1929), Jerrold J. Katz (1932–2002), Edward S. Klima (b. 1931), Robert B. Lees (1922–1996), and Paul M. Postal (b. 1936). The result of such changes was the so-called (by Chomsky himself) standard theory, presented in Chomsky (1965). The overall structure of the standard model is the following one: PS-rules and lexical insertion rules generate the deep structure both of simple and of complex sentences. The application of transformational rules to deep structure produces surface structures. PS-rules, lexical rules, and transformations form the syntactic component of grammar; deep structures are interpreted by the semantic component, giving the semantic representation of sentences; and surface structures are interpreted by the phonological component, giving the phonetic representation.

In Chomsky (1965), also the 'mentalist' interpretation of linguistic theory, explicitly defined as 'part of theoretical psychology,' was maintained and argued for in detail. Chomsky opposed competence, defined as "the speaker-hearer's knowledge of his language," to performance, which is defined as "the actual use of language in concrete situations." The linguist has to discover "the underlying system of rules" (i.e., the competence) "from the data of

performance" (Chomsky, 1965: 4). A grammar that correctly describes the competence of a native speaker of a given language is said to be descriptively adequate. A linguistic theory is said to be explanatorily adequate if it "succeeds in selecting a descriptively adequate grammar on the basis of primary linguistic data" (Chomsky, 1965: 25). The task of linguistic theory, then, becomes that of accounting for the properties of the LAD (Language Acquisition Device), i.e., the device that allows the child to construct a grammar from among a set of possible alternatives.

Generative Phonology

Generative phonology was discussed in several essays since the late 1950s and found its systematic presentation in Chomsky and Halle (1968). The starting point of generative phonology is that phonology is 'not-autonomous' from syntax: some phonological processes depend on morphological and syntactic structure. For example, the falling stress contour of *blackboard* is opposed to the rising one of *black board* because the former is a compound, hence belongs to the syntactic category N, whereas the latter is a Noun Phrase. Therefore the rules of assignment of stress contour must refer to syntactic surface structure (cf. Chomsky-Halle, 1968: chap. 2.1.). This is the reason why the phonological component is said to 'interpret' the syntactic component (see previous section). This strict interrelation assumed between the phonological and the syntactic level is quite contrary to the prohibition of mixing levels typical of post-Bloomfieldian structuralism (cf. section on this topic; Pike had already criticized this principle). Generative phonology considered the autonomous approach as a basic flaw of structuralistic phonology, both European and American, labeled 'autonomous phonemics': the notion itself of phoneme as conceived in such frameworks was rejected. Generative phonologists, on the one hand, took advantage from some difficulties in assigning which variants to which phonemes that had already been remarked upon within structuralistic phonology; on the other hand, they maintained that the assumption of an autonomous phonemic level often produces a loss of significant generalizations (the classical case was that of voicing of Russian obstruents, brought forward by Halle). Hence, generative phonology does not assume a phonemic level, but only a phonological representation and a phonetic representation. The former representation is derived from syntactic surface structure by means of readjustment rules; the latter is derived from the phonological representation by means of phonological rules, which apply in a given order. Both phonological and phonetic

representations are strings of word and morpheme boundaries and of feature matrices. In such matrices, columns are segments, and rows indicate the value of features. Features of generative phonology only partly overlap with Jakobson's ones (see section on Prague School): their number is higher (about two dozen vs. 12 or 14), and they are mainly defined on an articulatory rather than on an acoustic basis. Features are 'by definition' binary at the level of phonological representation, whereas they are not necessarily binary at the phonetic one. An essential part of generative phonology is the so-called theory of markedness (developing, but also essentially modifying, insights of Prague phonology): features, segments and rules are not on the same plane, but some of them are more natural in the sense that they are more frequent, are acquired by the child earlier than others, etc. This greater or lesser naturalness is accounted for in terms of unmarkedness vs. markedness of the concerned entities and rules.

Since the 1970s, alternative approaches to the strictly segmental or linear model of Chomsky–Halle (1968) have been developed. For example, feature values and segments were no more seen as necessarily in one-to-one correspondence, but it was assumed that in some cases a single feature can extend over more than one segment, and, vice versa, a single segment can subsequently take two opposite values of the same feature (autosegmental phonology). It was also assumed that the domain of application of phonological rules is not only determined by the syntactic surface structure and readjustment rules, but also that the phonological representation has a hierarchic structure of its own, not necessarily coinciding with the syntactic one (prosodic phonology).

The Impact of Generative Grammar

Generative grammar (or, more exactly, generative syntax) aroused great interest among linguists shortly after the publication of Chomsky (1957). This interest became still greater in the subsequent decade, especially after the appearance of Chomsky (1965) and also reached logicians and philosophers of language. Generative tenets were not accepted by everybody: quite the contrary, many of them were sharply criticized. However, the large majority of linguists felt obliged to take a position on them. The following tenets were especially the focus of discussion: (1) The mentalistic view of linguistics (cf. The Standard Theory), which was later called cognitive. (2) The assumption that linguistic theory has to deal with 'an ideal speaker–hearer,' within a 'homogeneous linguistic community': i.e., the social and communicative aspects of language do not influence its structure.

(3) The notion of Universal Grammar (UG), resuscitated by Chomsky (1965) with explicit reference to the tradition of *grammaire générale* starting with Port-Royal. From the early 1970s, UG essentially came to mean what he had earlier dubbed the 'language acquisition device' (LAD; cf. The Standard Theory): it was assumed to be universal since it would be shared by all human beings. (4) The postulation of two different levels of representation (deep and surface structure).

It is therefore possible to investigate the development of linguistic trends grown from the last 1960s according to the position they took with respect to the previously listed generative tenets. (1) Chomsky's cognitive view of linguistics was actually opposite the main structuralist trends, both in Europe and America, which conceived linguistics as an autonomous field. This new view was rejected, or at least dismissed as irrelevant, by some strictly formal approaches, such as Relational Grammar (see later discussion). It was, however, shared by the majority of trends during the last decades of 20th century, but often in a rather different way from Chomsky's. Indeed, although Chomsky simply assumed that to do linguistics *is* to do 'theoretical psychology,' many scholars maintained that linguistic explanations have to be traced back to more general psychological or cognitive factors, or, at least, they must be supported by independent psychological evidence. (2) Chomsky's low evaluation of social and communicative aspects of language contrasted with many earlier linguistic trends, even of the structuralist kind: e.g., Prague school defined language as a 'means of communication.' The view of language as a social phenomenon had been maintained at least since Meillet and it was strongly reaffirmed by scholars such as Uriel Weinreich (1926–1967) as an explicit rejection of Chomsky's views. Other opposition came from the pragmatic approaches to linguistic analysis that were developing within the philosophical tradition. More or less explicitly, all such trends opposed a 'social-communicative' view of language to the 'cognitive' one. (3) A revival of interest in the problem of linguistic universals had been already shown by researches such as Greenberg's; Chomsky's notion of UG clearly developed such interest in an unprecedented way. However, Chomsky's version of UG was not accepted by anybody: the different approaches to language universals were strictly linked with the different views of linguistics as a cognitive science and of relationships between language on the one side and social and communicative phenomena on the other. (4) Also the question of levels of representation was often linked to the problems of linguistic universals: several scholars equated 'deep structure' with UG, and

'surface structure' with cross-linguistic variation. These interpretations were misled, because both 'deep' and 'surface' structure had a specific technical value within a theoretical framework (see, e.g., Chomsky, 1975: 82). Nevertheless, they exerted a not negligible impact even on trends that were very distant from the Chomskyan one. Many of the debates between the different generative schools concentrated on the question if a distinction between whether a 'deep' and 'surface' structure is really necessary and on the nature of the 'deep' level.

In the following sections, trends stemming from generative grammar are distinguished from trends alternative to it. Such a distinction only refers to historical roots: the former trends were worked out by linguists originally (i.e., at the epoch of the standard theory) belonging to the generative group, the latter by scholars outside it. Nevertheless, several trends of the former group eventually became wholly alternative to the generative model.

Trends Stemming from Generative Grammar

Generative Semantics and Its Heritage

Generative Semantics (GS) was worked out between the 1960s and 1970s by scholars such as George Lakoff (b. 1941), James D. McCawley (1938–1999), Paul M. Postal (b. 1936) and John R. Ross (b. 1938). It was sharply opposed to the Extended Standard Theory (EST) by Chomsky and some of his followers. Both approaches shared a realistic view of linguistics and a multilevel approach to syntax, but their way of implementing such ideas was totally different. In their first works, generative semanticists rejected some basic assumptions of the standard theory: according to them, (a) deep structure was a useless concept, and (b) linguistic description must be semantically based. This semantic basis was sought in the reduction of linguistic categories to logical and/or psychological categories: semantic representation should be made to coincide with natural logic. In later works, it was assumed that semantic representation also includes typical semantic and pragmatic categories, such as focus or presupposition.

From the early 1970s, the leading ideas that had characterized the followers of GS were gradually abandoned, and each generative semanticist followed his own way. Lakoff first tried to work out a 'fuzzy' grammar, according to which grammatical categories are not discrete, but form a continuum from the noun at one end to the verb at the other. McCawley moved toward an empirical and somewhat skeptical approach to syntax: contrary to EST, McCawley kept on rejecting

any theory of language acquisition that did not take into account general cognitive properties. From this point of view, Cognitive Grammar by Ronald W. Langacker (b. 1942) and his associates could be considered as a legitimate heir to Generative Semantics.

From the middle 1970s, two linguists formerly belonging to the GS group, David M. Perlmutter (b. 1938) and Paul M. Postal, developed a theory called Relational Grammar (RG). RG completely abandoned the notion of transformation as an operation on hierarchically and linearly ordered phrase markers. It also explicitly rejected any aim at being 'psychologically real.' RG takes grammatical relations as primitives and represents clause structure as an unordered set of constituents that bear grammatical relations to each other. Grammatical relations may change from one level ('stratum,' in RG terminology) to another. Strata are not connected by means of transformations, but of Relational Networks, which show which different grammatical relations the constituents bear at different levels.

Fillmore's Case Grammar was often associated to GS, but it is essentially independent from it, even if both approaches wholly replaced the standard notion of deep structure. In Fillmore's view, the 'basic structure' of the sentence consists of the verb and an array of case relationships (see Fillmore, 1968). By 'case,' Fillmore does not mean a morphological category, but an 'underlying syntactic–semantic relationship.' The elements of the basic sentence structure are unordered.

'One-Level' Approaches to Syntax

Generative Semantics pushed the distance between 'deep' and 'surface' structure to its extreme, by identifying deep structure with semantic representation. RG preserved a multilevel approach to syntax. From the middle 1970s, other linguistic trends originated that took the opposite path, giving up the distinction between deep and surface structure and assuming a single level of syntactic representation. The first systematic proposals in this direction are due to Michael K. Brame (b. 1944). The most successful of such 'one-level' approaches were, however, LFG (Lexical-Functional Grammar) and GPSG (Generalized Phrase Structure Grammar). LFG was initiated by Joan Bresnan (b. 1945), a former Chomsky graduate student, and GPSG by a British scholar, Gerald Gazdar (b. 1945), who was later joined in his research program by other British and American linguists. On the one hand, GPSG and LFG share several assumptions: e.g., both avoid transformations and resort to other techniques to solve problems that standard theory dealt with in transformational terms. On the other hand, they

originated from and developed with rather different goals and concerns. LFG's original goal was the search for a 'realistic' grammar. GPSG was worked out mainly on the basis of formal concerns and had no special interest in building a 'psychologically real' grammar.

From EST to the 'Minimalist Program'

The syntactic theory worked out by Chomsky and his closest associates in the period from the late sixties until now had as its primary goal that of implementing the notion of Universal Grammar: the development of an adequate model of UG was seen as the proper goal of the cognitive view of language. This theory was called, during the 1970s, Extended Standard Theory (EST); in the 1980s, Principles and Parameters Theory (P&P) or 'Government-Binding Theory' (GB-Theory); from the early 1990s, the Minimalist Program (MP). Three works of Chomsky's could be considered the landmarks of each of these three phases: Chomsky (1973) for EST; Chomsky (1981) for P&P; and Chomsky (1995) for MP.

EST's main concern was the definition of restrictions on the functioning and on the format of syntactic rules. The first, decisive, step in this direction was the system of conditions on transformations of Chomsky (1973). More or less in the same period, Joseph E. Emonds (b. 1940) and Ray S. Jackendoff (b. 1945) formulated some important constraints on the format of transformational rules (Emonds) and phrase structure rules (Jackendoff). The great abstractness of all such conditions was assumed to be the proof that they could not possibly have been taught by adults or inductively discovered by the child. They were assumed to belong to Universal Grammar, namely the 'innate biological system' that is "invariant about humans" (Chomsky, 1975: 29). The innateness hypothesis, of course, contrasts with the actual cross-linguistic diversity. The Principles and Parameters approach was the first real effort made within the Chomskyan program to provide a systematic account of cross-linguistic differences. The universal features of language were dubbed principles, and the dimensions along which languages can vary, parameters. For example, the fact that a sentence in any language must have a subject would be a principle: but in some languages (e.g., Italian, Spanish, etc., as opposed to English, French, etc.) the subject may be 'null,' i.e., not phonetically realized. This option is called the 'null-subject-parameter': it has 'positive value' in Italian or Spanish, 'negative value' in English and French. Although principles are innate, the values of parameters are to be fixed on the basis of experience. 'Principles and Parameters' approach stimulated an amount of research much larger

than anything previously done within any other framework connected with generative grammar. In particular, the notion of parameter stimulated cross-linguistic investigation of several languages.

Chomsky, however, was more interested in the depth than in the breadth of explanation (in a sense, more to explanatory adequacy than to descriptive adequacy) and since the early 1990s developed the 'Minimalist Program.' The leading criterion of MP can be considered that of economy, namely resorting to the least possible number of entities and of levels of representation. Therefore, MP disposed of the levels of 'deep' and 'surface structure' and assumed Phonetic Form (PF) and Logical Form (LF) as the only levels of representation. Nevertheless, MP cannot be equated with 'one-level' approaches discussed in the preceding section. In fact, also this last version of Chomskyan generative syntax essentially assumes a very abstract relation between the phonetic and the semantic side of language: PF and LF are related by the computational system, i.e., a transformational apparatus. One of the main goals of MP is just to show *why* transformations exist: *prima facie*, they would seem to be antieconomical. The answer is that they exist to replace uninterpretable features, which are also antieconomical: by so doing, both imperfections erase each other. Natural language is therefore a perfectly economical system, and from this point of view, Chomsky maintains, it is very rare among other biological systems.

Trends Alternative to Generative Grammar

Functionalism Schools

The common feature of functionalism is the assumption that language structure is conditioned by its function as a means of communication. This approach was already taken by some structuralist scholars, such as Martinet, and especially the founder of Prague school, V. Mathesius, who distinguished between the formal (i.e., the grammatical) and the actual (i.e., the communicative) partition of the sentence. Mathesius's insights were taken over by Prague linguists of the subsequent generation, such as František Daneš (b. 1919) and Jan Firbas (1921–2000), who coined the term Functional Sentence Perspective to mean Mathesius's actual partition.

From the 1960s, the most significant functionalist schools developed as an explicit alternative to the formal paradigm of generative grammar: Functional Generative Description (FGD), mainly worked out by Petr Sgall (b. 1926) and his associates, which represents a further stage of Prague School linguistics;

Simon Dik's (1940–1995) Functional Grammar (FG) and Halliday's Systemic Functional Grammar (SFG). FGD proponents did not reject generative grammar as a whole, but maintained that it was too partial as an approach to language; on the other hand, they considered exclusively pragmatic approaches to be partial as well.

Despite their differences, all these functionalist schools share an important common core, the main points of which are the adoption of (a) Functional Sentence Perspective, and (b) a kind of Tesnière's valency grammar, in its original form or mediated through Fillmore's Case Grammar. Hence, their fundamental problem was to work out a device to explain the relationship between the system of Tesnière's roles (or Fillmore's 'deep cases') and the grammatical and communicative organization of the sentence.

Typological Linguistics

Typological linguistics since the early 1970s, mainly developed as an attempt to explain word order correlations stated by Greenberg (see the section titled 'The Beginnings of Typological Linguistics'), and it gradually replaced purely syntactic explanations with semantically and pragmatically based ones. It is therefore independent from generative grammar both in its origins and in its achievements. However, some insights stemming from generative grammar influenced typological studies, especially in the 1970s. For example, Winfred P. Lehmann (b. 1916) started from a syntactic model analogous to that of Fillmore's Case Grammar. He assumed an unordered 'underlying structure,' to be converted into a linearly ordered one by a rule with phrase-structure format: therefrom VO-languages vs. OV-languages would result (cf. Lehmann, 1973).

The most significant development of Greenberg's proposals about word order universals is due to John A. Hawkins (b. 1947), who showed that cases that appear as exceptions in Greenberg's treatment are actually not exceptions, if Greenberg's universals are reformulated in a 'complex' form. An example of such reformulation would be the following: "if a language is SOV, then, if it has AN order, it has also GN order" (cf. Hawkins, 1983: 64).

Two other key notions developed in the framework of typological linguistics, especially by Edward S. Keenan (b. 1937) and Bernard Comrie (b. 1947), are continuum and prototype: categories are no more defined, as in generative grammar, in terms of possessing or not possessing a given property, but as clusters of properties. If all such properties occur, the

concerned category is 'prototypical'; the deviations from the prototype are distributed along a 'continuum.'

Sociolinguistics

The label 'sociolinguistics' was firstly used in 1952 by the American Haver C. Currie (1908–1993), but it became widespread from about the late 1960s. In the last decades, this label ended in indicating a variety of researches, both of theoretical and applied kind, from 'ethnography of speaking' to 'language policy.' Between the 1960s and the 1970s, however, a sociolinguistic trend presented itself as an alternative approach to generative grammar.

The leader of this trend undoubtedly was William Labov (b. 1927), to whom the notion of variable rule is due. Variable rules have the format of PS-rules of generative grammar (more exactly, of *context-sensitive* PS-rules): their application or nonapplication, however, is not *categorical*, but it is conditioned by some probability factors, both of linguistic and extralinguistic (i.e., social, stylistic, regional) kind. By resorting to the device of variable rules, Labov was able to account for the different realizations of the same grammatical phenomenon across different social groups (a paradigmatic case was that of the contraction vs. deletion of the copula *be* in white vs. black American English speakers; see Labov, 1969).

The status of variable rules became a topic of intensive discussion. Do they belong to competence or to performance? Labov initially assumed that they are part of competence, but he eventually (in the 1970s) rejected the usefulness of such distinction. On the other hand, a radical revision of Chomsky's notion of competence had been proposed in 1968 by Dell Hymes (b. 1927), who replaced it by that of communicative competence, which indicates the speaker's ability to use language according to the different social and contextual situations. It can be remarked that, since the EST period, also Chomsky referred to a 'pragmatic competence' interacting with the grammatical one. Hence, the problem is whether grammatical competence is independent or not from 'pragmatic' or 'communicative' competence: Chomsky's answer was affirmative, whereas that of sociolinguistics and pragmaticists, negative.

Pragmatics

From the 1960s, pragmatics presented itself as an alternative to the Chomskyan view of language as a cognitive capacity fully independent from its use. Indeed, the roots of pragmatics lay earlier than generative grammar: the term had been created in 1938 by the philosopher Charles W. Morris (1901–1979) and the research field had as its initiators, between the

1950s and the 1960s, two British philosophers of language, John L. Austin (1911–1960) and H. Paul Grice (1913–1988) (neither of whom, however, used the word *pragmatics*). Austin maintained that speech is action (cf. Austin, 1962). The primary evidence for this is given by the utterances called performative by Austin, such as *I promise you to come*, by means of which I am not only *saying* something, but also *doing* it. Performative utterances are a kind of illocutionary act: examples of illocutionary acts are question, order, etc. According to Austin, a speech act, besides the illocutionary act, consists of the locutionary act (the uttering of given words and phrases) and the perlocutionary act (the intended effect of the speech act on the hearer). This classification of speech acts was partly revised by John R. Searle (b. 1932).

The original motivation of Grice's 'logic of the conversation' (which dates back to essays from the 1950s, eventually collected in Grice, 1989) was to show that there is no real divergence between the meaning of symbols such as \sim , \forall , \exists , etc., of formal logic and their counterparts *not*, *all*, *some*, etc., in natural language: the apparent differences of meaning are due to certain principles governing conversation, the conversational maxims. If I utter a sentence such as *Some students passed the examination*, I am undoubtedly saying the truth, even if *every* student did in fact pass the examination, but the hearer normally interprets it as meaning that only some students, and not all of them, passed the examination. This is due to the fact that I have violated the 'maxim of quantity': "make your contribution as informative as is required" (cf. Grice, 1989: 26). From my violation, the hearer has drawn the conversational implicature that only some students, and not all, passed the examination.

The analysis of speech acts and of logic of conversation are still today at the center of interest of pragmaticists. The interest in conversation also made pragmatics include a good deal of text linguistics, which originally started as a project to extend formal techniques of generative kind to units larger than sentences. In recent decades, text linguistics seems to have been replaced by the more empirical and informal conversational analysis, initiated by sociologists such as Harvey Sacks (1935–1975) or Harold Garfinkel (b. 1929), but later adopted by pragmatics-oriented linguists.

Two-Dimensional Semantics

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

When we ask whether a sentence is true or false, we are always asking with respect to a particular world. We are typically concerned about a sentence's truth value in the actual world, but we sometimes consider its truth value in other possible worlds as well. Thus the evaluation of any sentence is world-dependent in the sense that whether it is true (in a world) depends on the facts about that world. Context-sensitive sentences are also world-dependent in another quite different sense – what they mean depends on facts about the context, or world, in which they are used. For instance, *it's cold here* uttered in Pakistan means that it is cold in Pakistan, and when uttered in New Jersey means that it is cold in New Jersey. Two-dimensional semantics uses a formal apparatus from two-dimensional modal logic to characterize these two kinds of world-dependence. The two-dimensional framework has been applied to a variety of problems in semantics (indexicals and demonstratives and their interaction with modal operators), pragmatics (presupposition), and philosophy (accounts of the *a priori/a posteriori* distinction and the psychological/functional roles of thought). All of these applications depend on various assumptions, which are not implicit in two-dimensional modal logic, and many of which are controversial.

Modal logic allows that expressions may have different extensions in different possible worlds. For instance, it allows that the objects that satisfy a predicate in one world may differ from those that satisfy it in another. In one-dimensional modal logic, the rule that determines each expression's extension in every world, called its intension, is represented as a function from possible worlds into extensions. The intension of a predicate *F*, for instance, is a function that takes a possible world onto the set of individuals that satisfy *F* in that world, and the intension of a

singular term *t* is a function taking possible worlds to single individuals. Two-dimensional modal logic allows that a single expression may be associated with different one-dimensional intensions in different contexts, or worlds, of use. So it associates a two-dimensional intension with each expression, which is a function from possible worlds to one-dimensional intensions, or equivalently a function from ordered pairs of possible worlds into extensions (see Segerberg, 1973; Aqvist, 1973; van Fraassen, 1977 for expositions of a two-dimensional modal semantics for formal languages).

Since a two-dimensional intension takes pairs of possible worlds onto extensions, it has the resources to represent the two different kinds of world-dependence mentioned above. One of the worlds supplies the contextual elements needed to interpret context-sensitive expressions, and the other world supplies the context of evaluation. I will call the entity that plays the former role the world of occurrence, and the entity that plays the latter role the world of evaluation, although no terminology is standard.

Two-dimensional intensions can be represented in a matrix such as **Figure 1**, which gives a two-dimensional intension for a single expression, *s*. In the leftmost column of **Figure 1**, w^1 , w^2 , and w^3 represent possible worlds considered as worlds of occurrence. In the top row, these same three worlds are considered as worlds of evaluation. Suppose that *s* is the sentence *I am in San Francisco*. In w^1 , Ann is the speaker of this sentence and Ann is in San Francisco. She is also in San Francisco in w^3 , but

	w^1	w^2	w^3
w^1	T	F	T
w^2	F	F	F
w^3	T	T	T

Figure 1 Two-dimensional matrix.

not in w^2 . In w^2 , Beth is the speaker, but she is in London in all three worlds. In w^3 , Carl is the speaker, and Carl is in San Francisco in all three worlds. The cells of this matrix are filled in with truth values, since this is the appropriate extension for sentences. The row corresponding to w^1 tells us the truth value, in w^1 , w^2 , and w^3 , of the sentence s , considered as occurring in w^1 . In w^1 , Ann utters this sentence, so it is true just in the case where Ann is in San Francisco. Accordingly, this occurrence is true in w^1 and w^3 , but false in w^2 , as the matrix indicates. Similarly, the row corresponding to w^2 tells us the truth value in these three worlds of the sentence s , now considered as occurring in w^2 . Since Beth, not Ann, utters s in w^2 , this occurrence is true just in the case where Beth is in San Francisco. Since she is in London in all three worlds, the matrix contains an F in every cell in this row. The third row of the matrix tells us that the sentence s , considered as occurring in w^3 , is true in all three worlds. Since Carl is the speaker in w^3 , and he is in San Francisco in all three worlds, the row contains a T in every cell.

The matrix in Figure 1 only contains three possible worlds. But it is in principle possible to construct more comprehensive matrices, which contain many or all possible worlds. When the associated expression is a sentence, these more comprehensive matrices determine a number of propositions of theoretical interest. First, each row in such a matrix specifies a set of worlds in which the sentence s expresses a truth when it occurs in the world of that row. When the row in question is that corresponding to the actual world, the proposition it determines is the proposition s expresses. Another proposition of some theoretical interest is the set of worlds w in which the occurrence of s in w expresses a truth in w . If the matrix is constructed so that worlds w – w^n are arranged in numerical order on the top row and down the leftmost column, this proposition will be the diagonal of the matrix.

Applications

Different philosophers have modified this basic application of the two-dimensional framework in different ways for different purposes in semantics, pragmatics, philosophy of mind and language, and epistemology. Some philosophers follow the model of two-dimensional modal logic and offer a two-dimensional semantics for expressions (Kaplan, 1989). Others apply the two-dimensional apparatus to utterances (Stalnaker, 1978), or thoughts (Chalmers, 1996; Jackson, 1998) instead of or in addition to expressions themselves. Philosophers have also interpreted what I have called the world of occurrence and world

of evaluation in different ways. Some construe both as possible worlds (Stalnaker, 1978). For others, they are ordered n-tuples of contextually supplied elements (Kaplan, 1989) or maximal epistemic possibilities (Chalmers, 2004). Some philosophers think that the worlds of evaluation and worlds of occurrence are the same type of entity, and for others, different kinds of entities play the roles of worlds of utterance and worlds of evaluation within the same application of the two-dimensional framework (Kaplan, 1989; Chalmers, 1996, 2004).

David Kaplan has used the two-dimensional framework to provide a semantics for indexical and demonstrative pronouns. For Kaplan, indexicals and demonstratives are associated with characters, which are rules that determine their contents in different contexts of use. For instance, the character of *I* is the rule that says that an occurrence of *I* in a world of occurrence w refers to the speaker of that world of occurrence, and this individual is the content of this occurrence of *I*. Kaplan identifies worlds of occurrence (which he calls contexts of use) and worlds of evaluation (which he calls circumstances of evaluation) as ordered n-tuples of a speaker, time, location, and world.

Robert Stalnaker has suggested that the two-dimensional framework can explain how utterances acquire pragmatic effects. A pragmatic effect of an utterance is something that the utterance conveys beyond its semantic content, and which is determined both by the sentence uttered and the conversational context in which the utterance takes place. The conversational context supplies what Stalnaker calls a context set, which contains all beliefs and assumptions mutually held by all parties to the conversation, and against which the utterance is interpreted. Stalnaker proposes that we construct a two-dimensional matrix for a specific utterance and include in the matrix all and only those worlds in the context set. Typically, an utterance will express the same proposition in every world in the context set, because this set includes information about what the expressions in the utterance mean, how context-sensitive terms are to be interpreted, and which objects they refer to. However, in some cases the context set will not include all of this information, so that the utterance will express different propositions in different worlds. For instance, consider an utterance of *I am Bill Clinton*. This utterance either expresses or a necessarily true proposition, if the speaker is in fact Bill Clinton, or a necessarily false proposition otherwise. In neither case would the literal content of this utterance serve the typical purpose of ruling out some possibilities that the preceding parts of the conversation had left open.

Yet the utterance can serve this typical purpose if some participants in the conversation do not already know who the speaker is. In such cases, the context set for the conversation will include worlds in which the speaker is Bill Clinton, and worlds in which he is someone else. Thus the speaker's utterance of *I am Bill Clinton* expresses different propositions in different worlds in the context set. Which of these is the one the utterance conveys? Stalnaker suggests that it may be the diagonal of the two-dimensional matrix associated with this utterance. This is the contingent proposition that the speaker of a particular utterance is Bill Clinton, and this is intuitively the information conveyed by this utterance.

Stalnaker and Kaplan, among other philosophers, have also suggested that the two-dimensional framework does some strictly philosophical work. First, it appears to offer some account of the special epistemic properties of sentences like (1) (Kaplan, 1989; Stalnaker, 1978; but see Stalnaker, 2004).

(1) *I am here now.*

Uses of (1) express contingent truths, but (1) expresses a truth in every world of use. So (1) is in a certain sense an *a priori* truth – one need not know anything about the world of use to know that (1) expresses a truth in it. Although the different propositions it expresses in different worlds are all contingent, the diagonal of the two-dimensional matrix it determines will be necessary.

Martin Davies and Lloyd Humberstone have also applied the two-dimensional framework to a similar end, to explain a distinction between superficial and deep contingency earlier introduced by Gareth Evans. (Davies and Humberstone, 1980; Evans, 1979). Evans claimed that a sentence *s* is superficially contingent if and only if there exists a world *w* such that it is not the case that *s* is true in *w*, and *s* is deeply contingent if its truth depends on a contingent feature of the actual world. Typically, deep and superficial necessity coincide, but Evans argues that they need not always do so. Evans introduced this distinction to criticize Saul Kripke's claim that some propositions, such as (2) are both contingent and *a priori*.

(2) *The standard meter stick in Paris is one meter long.*

(2) is contingent because that very stick might have been less than one meter, but *a priori* because one can know (2) without appeal to experience. Evans argued that in all putative cases of the contingent *a priori*, the two notions of contingency come apart, and all such cases are merely superficially contingent. Davies and Humberstone apply Evans's basic distinction to

necessity rather than contingency, and claim that a statement *s* is deeply necessary if and only if the diagonal of the two-dimensional matrix for *s* contains every possible world, and it is superficially necessary if and only if the horizontal of the matrix for the row corresponding to the actual world contains every possible world. They do not attempt to use the two-dimensional framework to characterize *a priori* directly, though they do note that they know of no examples of *a priori* truths that are not deeply necessary. Since they also acknowledge some examples of deeply necessary *a posteriori* truth, they do not identify deep necessity, in their sense, with *a priori*.

David Chalmers and Frank Jackson have made the more ambitious identification of necessity on the diagonal with *a priori* (Chalmers, 1996; Jackson, 1998). Jackson in particular has suggested that there is only one notion of necessity and that the deep necessity Davies and Humberstone have defined is really *a priori* in disguise. For Chalmers and Jackson, thoughts as well as sentences have two-dimensional intensions, which they understand as functions from ordered pairs of centered worlds and uncentered worlds to truth values. A centered world is just a possible world with an individual and a time marked as its center. This two-dimensional intension determines both a primary and a secondary intension. The primary intension of a thought or sentence token *t* is a set of centered worlds *w* in which *t*, considered as occurring in *w*, is true in *w*, and would be found along the diagonal of a two-dimensional matrix. Its secondary intension is a set of uncentered worlds *w* in which *t*, considered as occurring in the actual world, is true in *w*, and would be found along the horizontal row associated with the actual world in a two-dimensional matrix. Chalmers and Jackson argue that primary intensions provide the following robust characterization of *a priori* knowledge: a thought is *a priori* if and only if its primary intension is necessary, that is, it contains every centered world (Jackson, 1998; Chalmers, 2004). Critics have attacked their view for what they see to be its revival of descriptivism about reference and its commitment to internalism about content (Soames, 2005; Byrne and Pryor, forthcoming; Stalnaker, 2004). Although Chalmers and Jackson embrace internalism about thought content, they deny that their application of two-dimensional semantics commits them to descriptivism.

Type versus Token

L Wetzel, Georgetown University, Washington, D.C., USA

© 2006 Elsevier Ltd. All rights reserved.

The Distinction

The distinction between a 'type' of thing and a 'token' of that type of thing, first described in those terms by C. S. Peirce, is an ontological one, akin to the universal/particular distinction (but arguably different from it; see below). Peirce pointed out that English, unlike German, has only one definite article, the word 'the'; this is the word type. Yet pick up any book in English and quite a few words on a particular page are apt to be 'the's; these are word tokens. Word tokens are concrete; they are spatiotemporal particulars such as inscriptions composed of ink, raised dots, light pixels, or utterances of phonetic sounds, or smoke signals, dots and dashes, etc. (Although not every sequence of three dots followed by three dashes followed by three dots, e.g., is a token of the Morse code distress signal; it may need to have been produced with a certain intention and in accordance with certain conventions. *see Speech*

Acts.) Each token has a unique spatiotemporal location, unlike a type, which is arguably an abstract object and does not.

In other words, the word 'word' is ambiguous. When we read that there are one million words in the *O.E.D.*, that Shakespeare's vocabulary consisted of 30 000 words, or that a two-year old should be able to say 20 words, we are to count word **types**. If the printer warns us to replace the ink cartridge every 100 000 words, we are to count word **tokens**. Different counting procedures point to different criteria of identity associated with the word 'word.' The same may be said of letters, phonemes, sentences, and most other linguistic items. There are only 26 letters in the English alphabet, yet there are more than 26 letters in (your concrete token of) this sentence. The former are types, the latter tokens. There are 44 phonemes in English, yet millions of phonemes uttered every day. The numbers reverse when it comes to sentences, for linguists assure us that there are many more, perhaps infinitely many more, sentence types than token sentences produced. The type-token distinction explains and is motivated by such considerations. It helps us to avoid fallacious inferences such as that if Shakespeare knew 30 000 words, then the

total number of words in my copy of Shakespeare's plays cannot exceed 30 000. (For more about words types, see Wetzel (2000).)

Its Usefulness

The type-token distinction is important to other branches of philosophy besides philosophy of language and logic. In philosophy of mind, it yields two significantly different versions of the identity theory: one identifies types of mental events with types of physical events (suggesting that the best way to understand mental activity is through neurology); the other merely says that every mental event is some physical event or other (but not necessarily a biological physical event, leaving the door open to an understanding of mental activity in terms of, say, programming) (see Block, 1980). In aesthetics, it is customary to distinguish works of art such as Mozart's Prague symphony (a type) from its many actual performances (tokens) (and also from its many interpretations, recordings, playings of recording, etc.) (see Wollheim, 1968; Wolterstorff, 1975). In ethics, actions are said to be right/wrong, but there is a dispute as to whether there are general principles that prescribe which types of actions are right/wrong or no general principles and only action tokens that are right/wrong.

Outside of philosophy, type talk is ubiquitous. That is, in scientific and everyday discourse we often speak in ways that apparently refer to types. When, for example, we read that the mountain lion disappeared from Iowa in 1867, but now is making a comeback there in the suburbs, we know no particular cat disappeared; rather, a type of cat, a species, did so. Similarly, to say the ivory-billed woodpecker is extinct, or that the banded bog skimmer is rare is not to be referring to one particular organism. The first gene that scientists found linked to an ordinary human personality trait (novelty seeking) is obviously a type of gene. These are examples of sentences where a **singular term** apparently refers to a type. But we also **quantify** over types with great regularity, as when a study claims that of 20 481 species examined, two-thirds were secure, 7% were critically imperiled, and 15% were vulnerable. Often we do both, as when it was claimed (in the 60s) that there are 30 particles, yet all but the electron, neutrino, photon, graviton, and proton are unstable. As with art (above), so with artifacts: when we read that the personal computer is more than 30 years old and is only now beginning to reveal its true potential, we do not think there is a particular dusty 30-year-old PC that is somehow improving. The chess move, we are told, of accepting the Queen's Gambit with 2...dc has been known since

1512, but Black must be careful in this opening – the pawn snatch is too risky. For a comprehensive treatment of reference to the many sorts of abstract objects we make in discourse, see Asher (1993).

Universals

The type-token distinction is akin to the universal-particular distinction, but there is some question as to whether types ought to be classified with the classic property examples of universals such as *being white*. If the hallmark of a universal is a capacity to have more than one instance, then types are universals. Types are generally also said to be abstract, just as universals are often said to be, in contrast to their tokens, which are concrete. However, if the hallmark of a universal is to answer to a predicate or open sentence the way *being white* answers to 'is white,' then types do not resemble universals, as they answer to singular terms (and quantifiers). This is amply illustrated in the preceding paragraph. That is to say, types seem to be *objects*, like numbers and sets, rather than properties or concepts; it's just that they are not particular concrete objects. If, then, we follow Frege (1977) in classifying all objects as complete and saturated and referred to by singular terms, and all properties as incomplete and unsaturated and referred to by predicates, then types would not fall into the same category as the classic examples of universals such as *being white*.

A Related Distinction

The type-token distinction may seem to license or encourage the following fallacious inference: This encyclopedia entry consists of (about) 2,000 words. Word types, or word tokens? It can't be word types, since my editor assures me that each and every 'the' counts as another word. Therefore it consists of (about) 2,000 word tokens. But then the encyclopedia entry itself would be a token – which it is not. (It is not the one in the Library of Congress in Washington, for example, as opposed to the one in the Bibliothèque Nationale in Paris.) The entry itself has many tokens, but is itself a type. As Simons (1982) points out, since it is abstract, it cannot be composed of concrete word tokens. So what are we counting when we count 2000 words? **Occurrences** of word types (see Wetzel (1993), for an account). That is to say, the word 'the' occurs quite a few times in this encyclopedia entry. The letter 'x' occurs three times in the formula '(∃x) (Gx & Hx)'. Now this may seem impossible; how can one and the same thing occur more than once in something without there being two tokens of it? See Armstrong (1986) and Lewis

(1986a), (1986b) for a debate on this point, and Wetzel (2006) for a rebuttal of Lewis. However, consider a sequence. The number 1 – the very same number – occurs several times in the sequence $\langle 0, 1, 0, 1, 0, 1 \rangle$. Even a concrete object can occur more than once. The same person occurs more than once in the sequence of New Jersey million dollar lottery winners, remarkably enough. The moral is that not every occurrence of a type is a token of it.

Do Types Exist?

Obviously, if types are universals then whether they exist is a matter of debate – a debate that goes back at least to Plato. Modern Platonists say they exist as transcendent abstract objects with no space-time location; see Bromberger (1989), Hale (1990), Katz (1981), and Wetzel (2002). Aristotelian realists say they exist as repeatable objects with numerous space-time locations; see Armstrong (1978), Wollheim (1968), and perhaps Zemach (1992) – although he calls himself a nominalist. Nominalists say they don't exist; see Goodman and Quine (1947), Quine (1953), Goodman (1977), and Bromberger (1992). With respect to universals, there is a third position, conceptualism, which tries to make do with mental objects such as ideas, or representations, in lieu of abstract ones, but since ideas also come in types and tokens, conceptualism only postpones the question – although see Szabo (1999). Some nominalists believe that if types are abstract objects, then, as is true for all abstract objects, we cannot have knowledge of them, because we cannot causally interact with them. Others take issue with a traditional argument for universals, according to which a red sunset and a red rose have something in common, and this something can only be the property of *being red*, so properties exist. Quine (1953), for example, objects that 'the rose is red because the rose partakes of redness' is uninformative – we are no better off in terms of explanatory power with such extra objects as *redness* than we are without them; perhaps a rose's being red and a sunset's being red are just brute facts.

Since Quine's attack on the traditional argument convinced many that that argument fails, the debate has shifted away from predicates. A realist nowadays is better off pointing to the fact, evidenced in the first four paragraphs above, that we talk as if there are types (even without appealing to predicates). That is, we frequently use singular terms for types, and we quantify over types in our theories. Quine (1953) has rightly stressed that we are ontologically committed to that over which we quantify. (For these reasons, although he rejected *redness*, Quine (1987: 217) held that expression types such as the word 'red' exist.) As

we saw, Frege emphasized that singular term usage is in indicator of **objecthood**. Since at least on the face of it we are committed to types in many fields of inquiry, it is incumbent upon the nominalist to 'analyze them away.' (Or to maintain that all theories that appear to refer to types are false – but this is a radical approach, as it comprises nearly all theories.)

The usual nominalist approach is to maintain that the surface grammar of type talk is misleading, that talk of types is just a harmless way of talking about tokens (see Bromberger, 1992). To say 'the horse is a mammal' is just to say 'all horses are mammals,' for example. The idea is to 'analyze away' apparent references to types by offering translations that are apparently type-free and otherwise nominalistically acceptable (see Goodman and Quine (1947) and Goodman (1977) for optimism). The problem is how to do this for each and every type reference (see Wetzel (2000) for pessimism). Sometimes the translation is obvious as with the horse example, where the predicate 'is a mammal' is true of the type and true of all the tokens too. But not all predicates are so cooperative. The grizzly bear is ferocious, but not every grizzly is ferocious. The word 'Gluck' is guttural, but its token inscriptions are not. For that matter, the written tokens have nothing observable in common with spoken tokens (if there is no type). Collective properties pose even more of a challenge. 'The ivory-billed woodpecker is extinct' is perhaps approximately equivalent to 'there are no more ivory-billed woodpeckers, although there used to be interbreeding populations of them,' which is arguably nominalistic. But it is very difficult to find a nominalistic paraphrase for 'Old Glory had 28 stars in 1846 but now has 50.' And it is nigh-on impossible to find a paraphrase for the claim mentioned above, that 'Of 20 481 species examined, two-thirds were secure, 7% were critically imperiled, and 15% were vulnerable.'

But the clincher for this nominalistic proposal (that all type-talk can be analyzed away in favor of talk of tokens) is that it presupposes that all types have tokens. Whether all types have tokens is a matter of some debate. Peirce, for example claimed it, but Chomsky (1957) denied it. It would violate laws of syntax that together have the consequence that there are more sentences than have been or will be instantiated.

Use Theories of Meaning

G Marti, ICREA & Universitat de Barcelona,
Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Traditional theories of meaning of the kind proposed by Frege, Russell, and the early Wittgenstein take to heart the idea that language is a system of symbols whose essential role is to **state** or to **represent** the goings on of the world and the mind. From the point of view of a traditional, or representationalist, approach to meaning, the fundamental area of inquiry about language and its significance has to do with the connection between linguistic items and the things they stand for or represent, things or facts. That is why two of the main focal points of traditional theories of meaning are the theory of reference – the exploration of the bond that ties expressions in a language to things in the world – and the theory of propositions – the discussion of the form and the constitution of what is expressed by utterances of sentences and their role in the determination of truth or falsity. So-called use theories of meaning can be best seen as reactions to the fundamental tenets of traditional theories: whereas traditional theories focus on what language represents and how it represents it, use theories search for the key to meaning in actual usage and linguistic practice.

The first strong appeal to use in the theory of meaning appeared in print in 1950, in P. F. Strawson's article 'On Referring.' Strawson's article is meant to be primarily a critical response to the analysis of sentences containing definite descriptions proposed by Bertrand Russell in his seminal paper 'On Denoting.' The merits or demerits of Strawson's specific objections to Russell's theory of descriptions will not be addressed here. The important point for our purposes is rather the positive outlook on meaning that Strawson's remarks suggest. In criticizing Russell, Strawson (1971: 9) contends that "to talk about the meaning of an expression or sentence [is to talk about] the rules, habits, conventions governing its correct use, on all occasions to refer or to assert". Although rather programmatic in character,

Strawson's remarks point towards a conception of the significance of linguistic expressions that departs radically from the Frege–Russell–early Wittgenstein approach for, according to Strawson, neither the things that terms stand for, as Russell and Wittgenstein would have it, nor the conceptual material associated with expressions – the sense – that in turn determines what those expressions stand for, as Frege would have it, constitute appropriate answers to the question 'What is the meaning of X?' On the contrary: "to give the meaning of an expression is to give general directions for its use" (Strawson, 1971: 9).

Traditional theories of meaning, with their emphasis on reference and propositions, leave out of the realm of semantic inquiry a host of expressions whose significance cannot be doubted. For what does 'hello' refer to? What proposition do we express, what fragment of the world do we represent, when we say 'hello'? If we do express a proposition, under which conditions is it true or false? Unlike traditional theories, use theories of meaning would explain the meaning of 'hello' and similar expressions by appeal to the rules and conventions that indicate their appropriate use. But it is not only expressions such as 'hello,' 'ouch,' or 'pardon' that, according to use theorists, are left behind by traditional approaches. J. L. Austin argued that this is so for a class of sentences, which he characterized as 'performative,' that look grammatically like any other subject-predicate or subject-verb-object sentence that we use to represent a fragment of the world, such as 'It is raining' or 'The train is late.' We use the latter to tell the way things are and consequently when we utter them we say something true or something false. Performative utterances, on the other hand, do not state or represent the way things are. When we utter a performative, Austin argues, we certainly say something significant, yet it is neither true nor false. The uses of sentences that Austin is thinking of are utterances of, for instance, 'I name this ship *Queen Elizabeth*,' 'I do [take this man to be my husband],' 'I promise to be at the party,' 'I apologize.' According to Austin what all these sentences have in common is that by uttering one of them we do not report or describe

a state of affairs, an event or an action. Uttering one of those sentences is actually **performing** an action. Uttering a performative is a speech act. By saying 'I do,' as Austin (1961: 235) puts it, "I am not reporting on a marriage, I am indulging in it". Because utterances of performatives do not function like statements, the question of truth or falsity does not arise with regard to them. However, there are, Austin points out, ways in which performatives can succeed or fail. For instance, if the utterer does not have the authority to give a name to a ship, her utterance of 'I name this ship *Queen Elizabeth*' does not succeed in performing the intended action. For an utterance of a performative to be satisfactory some felicity conditions must be in place.

It is tempting to think that Austin is highlighting a phenomenon circumscribed to a well-delimited class of utterances, and that for the vast majority of natural language sentences the traditional representational picture applies smoothly. That is not so: what Austin is proposing is not just a specific treatment of a peculiar phenomenon but rather a different conception of meaningfulness. On Austin's view, statements, as much as performatives, are essentially speech acts and are therefore subject to similar conditions of adequacy and success. Suppose we utter a statement such as 'John's children are all very polite' and John has no children. According to Austin, the situation as regards that statement parallels a performative utterance such as 'I promise I will sell you this piece of land' when the piece of land in question does not exist. In the latter case we would say that the sale is void; and in the former case we should say that the statement is void also. Both performatives and statements are subject to the question 'Is it in order?' If the answer is negative, the performance fails. And if the answer is positive, then both performatives and statements are subject to further questions of felicity. Those questions may take different forms depending on the type of speech act: if it is a warning, the question is whether it was justified; if it is a piece of advice, the question is whether it was sound; if it is a statement, the question is whether it was true; in every case, although in different forms, those questions "can only be decided by considering how the content ... is related in some way to fact ... we do require to assess at least a great many performative utterances in a general dimension of correspondence with fact" (Austin, 1961: 250). In this way Austin (1961: 251) takes statements "off their pedestal" and offers a uniform picture of meaning that appeals essentially to our usage of expressions to do things.

Among use theorists we cannot forget Ludwig Wittgenstein, the coiner of the motto 'meaning is

use.' In the first part of the *Philosophical Investigations*, completed in 1945 although not published until 1953, Wittgenstein reacts strongly against the traditional conception of meaning. In fact, Wittgenstein is reacting against his own earlier views presented in the *Tractatus Logico-Philosophicus*. Wittgenstein's account of meaning in the *Tractatus*, with its characterization of the proposition as a picture of a fragment of the world, is the paramount example of a traditional representationalist approach. In the *Investigations*, by contrast, Wittgenstein rejects the explanatory project of Frege and Russell: neither the Fregean senses that are supposed to determine the objects expressions refer to, nor the things that on Russell's (and the *Tractatus*'s) approach are directly and conventionally associated with signs, give life and significance to language: only its use gives meaning to a sign.

To understand the kind of practice we engage in when we use a language as members of a speakers' community, Wittgenstein appeals to the metaphor of playing a game. For Wittgenstein, learning a language, like playing tennis, consists in becoming competent at a rule-governed practice. It does not consist in explicitly learning the rules, having them, so to speak, written in one's mind; being able to play tennis, or being able to speak and understand a language consists in being proficient at doing something according to the rules.

Different use-oriented approaches to meaning criticize the traditionalist stance for disregarding the fact that language is a tool that we use to do things, that speaking and understanding a language is a matter of engaging in a practice, and that, consequently, the key to meaning is to be found in the way language users employ language. But how radical the departure from the traditional stance is depends on how the motto 'meaning is use' is interpreted. On the one hand it may be interpreted as a claim about what gives expressions the meaning they have. The appeal to use is then a reminder that languages are social institutions and that it is by virtue of usage that expressions are connected to their meanings. From this point of view, it is not inappropriate to say, for instance, that by virtue of its use, the word 'dog' means a certain concept or that its meaning consists in naming a species. So interpreted, the claim that meaning is use is fundamentally presemantic, it is not a claim about what constitutes the meaning of expressions. So conceived, use theories of meaning are not opposed in essence to traditional theories, although by stressing the meaning-conferring role of use they expand the horizons of the traditional stance, for they make room in semantic theory for expressions whose meaning cannot be cashed out in terms of what and how

they represent objects or states of affairs, and they do not disregard aspects of meaning that are not truth conditional.

A more radical way of interpreting the claim that meaning is use is as a semantic claim, i.e., a claim about what constitutes the meaning of linguistic expressions. From this point of view there is nothing over and above the way an expression is used that can qualify as its meaning. Use is not just what makes an expression have a meaning; it is **all there is** to meaning. Some varieties of deflationism take this stance. Thus, for instance, in Horwich (1998: 6) we read: "The meaning property of a word reduces [to] . . . the property that every use of the word is explained in terms of the fact that we accept certain specified sentences containing it."

The radical interpretation of the claim that meaning is use faces a number of objections. Here I will focus on only two general challenges (for discussion, see Horwich, 1998). First, it may be argued that the idea that use determines the meaning of an expression puts the cart before the horse. Intuitively there is a distinction to be drawn between correct or incorrect usage. No matter how pervasive the use of 'irregardless' is, it is an incorrect expression. The very idea of incorrect, but extended, use seems to entail that it is because expressions do have a meaning, over and above the way in which they are used, that we can talk about correct or incorrect usage. Meaning determines (correct) use and not vice versa, so it seems that the claim that meaning is constituted by use has difficulties accounting for the normative aspect of meaning.

Second, the idea that all there is to the meaning of an expression is its use does not leave room for what appears to be a legitimate possibility: a speaker may be competent in the use of an expression, she may know the situations in which it is appropriate to use it and how to react to uses of it, and yet she may not know the meaning of the expression in question. The possibility is, in fact, less far fetched than it appears. Consider the case of Helen Keller: blind and deaf from an early age, she explains in her autobiography

how she and her family had developed a rather good system of symbols to communicate their needs and wishes: when she wanted bread, she made a sign, when she wanted ice cream, she made another sign. Her mother had ways to tell Helen what she needed, and Helen would go and get it for her: Helen had mastered the use of a system of symbols. Nevertheless, when she was seven her teacher, Miss Sullivan, once spelled on Helen's hand the sign for water while Helen felt water with her other hand, and that was the moment that she describes as "learning the key to all language." What could she possibly have discovered that she didn't know before? It surely was not how to use the sign 'water' but rather, and quite simply, that 'water' stands for water. Now, it may be argued that learning that 'water' can be used to refer to water is indeed learning something new about the use of 'water.' But then it would appear that even from the point of view of use theories of meaning we need to be sensitive to the fact that expressions represent things and that it is the relation between words and things that makes it possible for us to talk about the world.

Use versus Mention

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Generally, the distinction between using something and mentioning it is completely straightforward. For

instance, there is all the difference in the world between mentioning, or talking about, a lawn mower, and using it to mow the lawn. Yet the distinction can engender some confusion when it comes to mental and linguistic representations, and this is what philosophers and linguists have in mind when they

talk about the use/mention distinction. The distinction between mentioning a word, picture, or mental representation, and using it to communicate or entertain a thought is best illustrated by example. Sentence (1) uses the word 'Boston,' and sentence (2) mentions it.

- (1) Fred is from Boston.
- (2) 'Boston' has two syllables.

Philosophers customarily put a word (or complex expression) inside quotation marks, to form its 'quote name,' if they want to mention it instead of using it, as in (2). Linguists, in contrast, typically use italics, labeled bracketing trees, or a phonetic alphabet to mention an expression, as in (3a–c).

- (3a) *Boston* has two syllables.
- (3b) [_{NP} Boston] has two syllables.
- (3c) bɛs tən has two syllables.

An advantage of the philosopher's convention is that we may easily form the quote name of a quote name simply by enclosing the quote name itself in quotation marks, as in (4):

- (4) "“Boston”" is the name of a word, not a city.

We can also mention an expression without using any of these devices, as in (5) and (6).

- (5) The first line of Gray's *Elegy* states a proposition.
- (6) Samuel Clemens's pen name is derived from a riverboat driver's call.

Example (5) uses an expression, 'the first line of Gray's *Elegy*,' to mention the linguistic expression it denotes, namely, 'The curfew tolls the knell of parting day.' Similarly in (6), the expression 'Samuel Clemens's pen name' is used to mention another linguistic expression, namely 'Mark Twain.'

When we talk more systematically about a particular language, as we do in describing its syntax or semantics, we observe the related distinction between object language and metalanguage. The object language is the language under discussion, and the metalanguage is the language we use to talk about the object language. In some cases, the object language and the metalanguage are different languages, as in (7), but the object language and the metalanguage can be the very same, as in (8).

- (7) 'Le chien est sur la chaise' is true if and only if the dog is on the chair.
- (8) 'The dog is on the chair' is true if and only if the dog is on the chair.

Sentences (7) and (8) mention sentences of the object language (enclosed within quotation marks). The metalanguage, in both cases English, is the language used to state the truth condition of sentences in the object language.

Sentences that mention themselves, such as (9), can give rise to paradox.

- (9) This sentence is false.

Sentence (9) appears to have the paradoxical property of expressing a truth if and only if it expresses a falsehood. Many sentences that mention themselves are innocent in this respect, such as (10):

- (10) This sentence contains five words.

The paradox only arises for sentences that self-ascribe semantic properties such as truth or falsehood. A central project of a theory of truth is to resolve this paradox.

So far, the use/mention distinction seems easy to keep straight: How could someone confuse the name 'Boston' with the New England city itself? Yet philosophers sometimes charge one another with confusing use and mention of linguistic expressions. Such confusion typically results in mere obscurity, as it does in this passage from Leibniz, as translated by C. I. Lewis.

Two terms are the same if one can be substituted for the other without altering the truth of any statement. If we have A and B and A enters into some true proposition, and the substitution of B for A wherever it appears, results in a new proposition which is likewise true, and if this can be done for every such proposition, then A and B are said to be the same; and conversely, if A and B are the same, then they can be substituted for one another as I have said (Lewis, 1960: 291).

Richard Cartwright has suggested that the apparent use/mention confusion here makes it difficult to see exactly what Leibniz intended to say in this passage (Cartwright, 1971: 119). Perhaps Leibniz meant that A and B are the same if and only if **their names** can be intersubstituted into any statement without altering the truth value of the proposition that the statement expresses. If this was what he meant, then in some places he should have **mentioned** the names of A and B rather than **using** them, as he in fact did.

In other cases, however, use/mention confusions may ground substantive philosophical mistakes. One such mistake is the familiar confusion of objects with our ideas of them. This mistake arises particularly for philosophically problematic entities such as the number three and Beethoven's Ninth Symphony. It is obvious that they are not concrete objects, but less obvious what else they could be. Since we clearly have ideas of these objects, some have suggested that we identify the objects themselves with our ideas of them. cursory reflection reveals that this suggestion cannot be correct, since these entities have properties

that ideas could not have. Ideas, for instance, cannot be the cube root of 27 or played frequently by the Berlin Philharmonic. Plausibly, what lies behind this suggestion that objects like these are really ideas in our heads is a confusion of our mental representations of these objects with the objects themselves. Like the confusion of the word 'Boston' with the city of Boston, this is a straightforward confusion of use with mention.

Vagueness: Philosophical Aspects

R Keefe, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Hallmarks of Vagueness

Much of language is vague, including expressions such as ‘heap,’ ‘bald,’ ‘red,’ ‘child,’ and ‘hungry.’ Although the exact criteria of vagueness are controversial, we can say that, at least in general, vague predicates have borderline cases and seem to lack sharp boundaries and well-defined extensions. A dieting man, Don, may at times be a borderline case of ‘thin’ – it is unclear whether or not he is thin. And the apparent lack of sharp boundaries to the predicate is exhibited in the fact that there does not appear to be a sudden instant during his successful diet at which Don becomes thin. Though we frequently call assertions vague if they don’t supply us with enough information (e.g., ‘I’ll visit next week’), this is a different sense of ‘vague’ from that at issue here.

Vague predicates give rise to sorites paradoxes, of which the most famous is the paradox of the heap. If you have a heap of sand, and you remove a single grain, then the result will still be a heap. But then, suppose we take a heap of sand and remove grains one by one; repeated applications of that principle imply absurdly that the solitary last grain is a heap. The vagueness of other predicates accounts for the plausibility of comparable principles that can figure in sorites paradoxes, such as ‘if someone is a child at time t , then she/he is a child 10 minutes later’ or ‘if someone of height h is tall, then so is someone one-hundredth of an inch shorter.’

Typical vague predicates also exhibit what is known as ‘higher-order vagueness.’ Not only does ‘tall’ have borderline cases at heights between the definitely tall and the definitely not-tall, but the set of such borderline cases does not seem to have sharp boundaries either. Just as it is not plausible to think there is a precise instant at which Don becomes thin, there seems to be no precise instant at which Don becomes borderline thin, or one at which he ceases to be borderline thin and becomes definitely

thin. Perhaps, then, the borderline cases of ‘thin’ themselves have borderline cases – borderline borderline cases of ‘thin.’ And, moreover, those borderline borderline cases do not seem to be sharply bounded either, suggesting a hierarchy of borderline cases corresponding to the apparent lack of sharp boundaries at all levels.

Finally, note that other elements of language besides predicates are also vague: consider, for example, ‘hurries,’ ‘quickly,’ ‘many,’ ‘very’ and ‘the nicest man.’ Analogues of the central hallmarks of vagueness could be described in relation to these kinds of expressions.

Three Philosophical Debates About Vagueness

First, is vagueness eliminable? Many have thought not. Vague predicates seem to be an unavoidable presence in our language. As Russell (1923) argues, the application of, say, ‘red’ is based on unaided sense perception, and so it surely cannot be applicable to only one of an indiscriminable pair. But this thought is enough to generate a sorites paradox by considering something that changes from red to yellow through a series of changes too small for us to detect. Similarly, it can be important to have a word, like ‘tall,’ to pick out a vague range of a measurable quantity, like height. The applicability of other useful vague predicates can depend on several dimensions of variation – whether someone counts as ‘big’ can depend on both their height and their weight – or it can depend on a range of dimensions that is itself not well-defined – such as ‘nice’ applied to people.

Second, is there ontological vagueness? It is controversial whether it is only language and thought that can properly be called vague, or whether there can be vague objects or other vague entities. Russell thought that only representations could be vague, and Evans (1978) has argued that the idea of vague objects is not coherent, but other philosophers have attempted to make sense of the idea. This issue of metaphysical vagueness is often tackled independently of the

attempt to give a theory of linguistic vagueness, with which we are concerned here.

Third, does vagueness have implications for logic? Many have thought that vagueness poses a challenge to classical logic. If Don is a borderline case of thinness, it is tempting to maintain that 'Don is thin' is neither true nor false, which is incompatible with the principle of bivalence. And the apparent lack of sharp boundaries to vague predicates is in tension with the well-defined extensions required for classical logic.

Philosophical Theories of Vagueness

A theory of vagueness faces the task of solving the sorites paradox and determining the logic and semantics of vague language.

One approach is to reject classical logic, acknowledging that borderline case predications are neither true nor false, and specifying that they have some intermediate truth-value. For example, we could adopt a three-valued logic and explain the apparent lack of sharp boundaries between the Fs and the non-Fs in terms of the range of cases between these two poles (see Tye, 1994). Or we could recognize a full range of intermediate truth-values corresponding to degrees of truth: in the region of transition from not-thin to thin, Don may count as thin to different degrees, gradually increasing from the minimum, 0, to the maximum, 1. This kind of degree theory calls for an infinite-valued logic (see Machina, 1976; for a non-standard degree theory, see Edgington, 1997).

One common objection to this kind of approach is that it merely replaces classical logic's sharp boundary between truth and falsity with other sharp boundaries between adjacent members of the new set of truth-values. So, for example, according to a three-valued logic, there will be a first instant at which Don ceases to be falsely called thin becomes borderline thin, and with a degree theory, there will similarly be a first instant at which he is thin to some degree greater than 0. Intuitively, there are no such sharp boundaries either. One way of putting the worry is that these views of vagueness cannot accommodate higher-order vagueness. Some theorists, however, (e.g., Tye) have attempted to defend a many-valued theory that is not committed to sharp transitions by appealing to the vagueness of the metalanguage in which the theory is formulated.

An alternative approach to vagueness involves accepting sharp boundaries at the first level and embracing classical logic. This epistemic view maintains that borderline case predications are either true or false – we just do not know which (see Williamson, 1994). Similarly, there is a particular instant at which

Don becomes thin – we just do not know when it is. This solves the sorites paradox by denying its main premise, that is, the principle that taking a grain away from a heap will leave you with a heap. Classical logic is preserved in its entirety. The apparent lack of sharp boundaries is merely apparent, and vagueness is a matter of ignorance. Williamson (1994) has defended such a theory and provided a detailed explanation of why we are ignorant by appealing to the idea of a margin for error. If I know that someone of height h is tall, then someone of height $h - e$ is tall, where e is less than the margin required for my belief to be reliable. It follows that I can't know that someone slightly above the boundary is tall nor, by a parallel principle, can I know that someone slightly below it is not tall; so I can't know that the boundary falls between these two close points.

The supervaluationist theory of vagueness takes a different approach to the semantics of vague language while preserving the theorems and inferences of classical logic (see Fine, 1975; Keefe, 2000). According to this theory, 'Don is thin' is true (false) if and only if it is true (false) on all ways of making it precise, i.e., with all reasonable ways of drawing the boundary to 'thin.' If Don is borderline thin, that sentence is true on some of those ways and false on others, so it is neither true nor false. Before his diet, however, Don was definitely not thin, and it counted as false that he is thin according to supervaluationism, because any boundary that ruled him as thin at that time is not an acceptable way to make 'thin' precise. To see how the law of excluded middle still holds, despite the failure of bivalence, consider the instance 'either Don is thin or he isn't' in the case where he is borderline thin. On every way of making 'thin' precise, that disjunction comes out true, even though on some of those ways it is the first disjunct that is true, and on others it is the second disjunct. The main premise of the sorites paradox comes out false, on the other hand: on every way of drawing the boundary to 'heap,' there is some grain the removal of which turns a heap into a non-heap. But 'heap' is nonetheless not sharply bounded, because there is no particular grain whose removal marks the boundary to 'heap'; different grains mark the boundary for different ways of making 'heap' precise.

Other solutions to the sorites paradox have been proposed in addition to those embedded in the influential theories just sketched. Contextualist accounts appeal to changes in context between the assessments of different predications along a sorites series (see, e.g., Graff, 2000). Now, vague terms are typically context-dependent; whether someone counts as thin or something counts as a heap can depend on the context in which it is considered. But vagueness does not

straightforwardly reduce to context-dependence, because if we fix the context, a vague term will still have borderline cases and be susceptible to a sorites paradox. Nonetheless, the contextualist approach attempts to close the gap between these phenomena with a complex and subtle treatment of context-change.

The nihilist response to the sorites paradox is one of the few that does not involve denying its main premise (see Unger, 1979). The meaning of 'heap' dictates that a heap will always survive the removal of a single grain, but the paradoxical argument does not take hold because there are no heaps. Run the case by adding grains one at a time to a single grain (adding a single grain to something that isn't a heap doesn't create a heap) and you have a sound argument with a true conclusion. This nihilist position thus renders our vague predicates empty; there are no tall people, thin people, or red things either.

To summarize, vague predicates typically have borderline cases, apparently lack sharp boundaries, and are susceptible to sorites paradoxes. For example 'is a ripe fruit' has borderline cases – a banana that is not definitely ripe and not definitely not ripe – and there is not typically a sharp point at which a fruit becomes ripe. And we can construct a sorites paradox with the notion using a premise such as 'if a fruit is not ripe at some instant, then it is not ripe one second later.' Vagueness, recall, is not merely an eliminable defect of our language; no precise replacement for 'ripe' would be usable in practice. And it poses a challenge to principles of classical logic, increasing the urgency of providing a theory of vagueness. Theories adopting a multi-valued logic will assign some intermediate truth-value between truth and falsity to the statement that our borderline-ripe banana is ripe. An epistemicist theory will maintain that such a statement is either true or false, but we just don't know which. And the supervaluationist will claim that it is neither true nor false, because it is true on some ways of making 'ripe' precise and false on others. Each of these views solves the sorites paradox by denying

that the main premise is completely true, though no matter what they do to explain this, it is hard to dismiss the intuitiveness of a premise like 'if a fruit is not ripe at some instant, then it is not ripe one second later.'

Verificationism

M Beaney, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Verificationism is the view that the meaning of a (synthetic or empirical) statement is given by its method of verification. A sentence, as used on a given occasion to make a (synthetic or empirical) statement, has meaning if and only if its truth or falsity can – in principle – be determined by experience. Verificationism was the central doctrine of logical positivism (also called ‘logical empiricism’), a movement that originated in the work of the Vienna circle in the early 1930s and received its classic statement in A. J. Ayer’s *Language, truth and logic* (1936). Although subject to devastating criticism in the 1940s and 1950s, the motivation behind verificationism has continued to influence philosophers ever since, most notably, in the work of W. V. O. Quine and Michael Dummett. Indeed, the basic positivist impulse – to reject anything that is not grounded in sensory experience – goes back at least to David Hume, and has been a significant feature of the philosophical landscape throughout the modern era. Hume’s famous words at the very end of his *Enquiry concerning human understanding* are often taken as the definitive statement of the underlying positivist view:

If we take in our hand any volume; of divinity or school metaphysics, for instance; let us ask, *Does it contain any abstract reasoning concerning quantity or number?* No. *Does it contain any experimental reasoning concerning matter of fact and existence?* No. Commit it then to the flames: for it can contain nothing but sophistry and illusion.

The repudiation of metaphysics was characteristic of logical positivism, too, and this was rooted in the doctrine of verificationism.

The Analytic/Synthetic Distinction

Central to logical positivism was the distinction between analytic and synthetic statements – corresponding to Hume’s distinction (implicit in the passage just quoted) between relations of ideas and matters of fact. According to the logical positivists, a statement is analytic if and only if its truth or falsity is determined solely by the meaning of its constituent terms. ‘All bachelors are unmarried men,’ for example, was seen as true in virtue of the meaning of the term ‘bachelor.’ Analytic truths were regarded as both necessary and *a priori*. Their necessity was seen to lie

in their tautological nature, a view that the logical positivists took from Ludwig Wittgenstein. Since, on their account, analytic truths could be judged to be true merely by knowing their meaning – without needing to consult the world in any way – they were also regarded as *a priori* truths.

A statement was seen as synthetic, on the other hand, if it is not analytic, and synthetic truths were regarded as both contingent and *a posteriori*. It was in explaining synthetic statements that the doctrine of verificationism was formulated. According to this doctrine, the meaning of such a statement lies in its method of verification. A statement is meaningful if and only if its truth or falsity can in principle be determined by experience, that is, be derived in some specified way from the truth of one or more observation statements – statements that record the direct result of an observation. This characterization immediately raises two questions. What exactly is the relationship between the statement whose truth-value is to be determined and the observation statements? And what exactly is an observation statement?

Observation Statements

Let us take the latter question first. There was much debate among the members of the Vienna circle in the 1920s and 1930s about the foundations of empirical knowledge and the correct form that observation statements – or ‘protocol sentences,’ as they were called – should take. In his *Aufbau* of 1928, influenced by Bertrand Russell’s appeal to sense data in *Our knowledge of the external world* (1914), Rudolf Carnap sketched a ‘reconstruction’ of our empirical knowledge on a phenomenalistic base. But he also offered the possibility of a physicalistic reduction, reflecting his rejection of the idea that there is any privileged ontology. (Cf. Beaney, 2004: § 4.) Despite this, however, a physicalist language soon became seen as the preferred form in which the protocol sentences were to be expressed, although debate raged about the relations between the physical and the psychological, and indeed, about the very idea of a ‘foundation.’ (See, e.g., Carnap, 1932/1933; Neurath, 1932/1933; Schlick, 1934; Ayer, 1936/1937. For an excellent account of the debate, see Uebel, 1992.)

In A. J. Ayer’s work, however, influenced by Russell and the British empiricists, observation statements were construed as statements about sense data, and material objects – and indeed, other minds – were seen as logical constructions out of them. The project of logical construction was all the rage among analytic

philosophers in the early 1930s (see especially Wisdom, 1931–1933), but it gradually became clear just what difficulties it faced. (For a critique, see, e.g., Urmson, 1962, ch. 10, and more recently, Soames, 2003, I, ch. 7.) More fundamentally, the whole appeal to sense data proved problematic, as the very idea of sense data came under increasing fire in the years that followed. (See especially Austin, 1962, and the essays in section II of Swartz, 1965.)

Strong Verification

Problems arose, then, about the nature of observation statements. But even if we leave these aside, and assume that there is a legitimate class of observation statements, such as expressed by sentences of the form ‘The *A* in front of me is a *B*,’ there remains the question of specifying the relationship between the synthetic statement whose truth-value is to be determined and the observation statements. The relationship was seen as one of verification. But what is it to verify a statement? A distinction came to be drawn between ‘strong’ and ‘weak’ verification. In the strong sense, a statement is verifiable if and only if, as Ayer put it, “its truth could be conclusively established in experience” (1946: 12). More precisely, the notion might be defined as follows: a statement *S* is strongly verifiable if and only if there is some set of observation statements which logically entail *S*. The obvious problem with this, however, is that universal generalizations cannot be strongly verified, since no (finite) set of observation statements, ‘*A*₁ is *B*,’ ‘*A*₂ is *B*,’ . . . ‘*A*_{*n*} is *B*,’ entails ‘All *As* are *B*.’ Even if all the *As* that we have so far experienced have been *B*, there remains the possibility that the next *A* we experience will not be a *B*. Yet many universal generalizations are clearly meaningful, so we cannot accept strong verifiability as the criterion for meaningfulness.

Strong Verification and Strong Falsification

This might suggest that we should talk not of verifiability but of falsifiability (as Karl Popper was to urge). A statement *S* is strongly falsifiable, we might then say, if and only if there is some set of observation statements which logically entail not-*S*. Saying that a statement is meaningful if and only if it is strongly falsifiable legitimizes universal generalizations, since it only takes one observation statement as a counterexample to falsify a universal generalization. However, we are then faced with the corresponding problem of existential statements, such as ‘There is at least one *A* that is not a *B*’ (the contradictory of ‘All *As* are *B*’). Finding an *A* that is not a *B* may verify this statement, but no observation statement could falsify

it. Finding an *A* that is a *B* neither verifies nor falsifies it. To falsify it we need to be sure that *all As* are *B*, but as we have just seen, this is not entailed by any set of observation statements that we may have made up to now.

The obvious response to both these problems is to say that a statement is meaningful if and only if it is *either* strongly verifiable *or* strongly falsifiable. But this, too, faces problems. First, there are statements involving more complex or different kinds of quantification, such as those expressed by sentences of the form ‘For every *A*, there is a *B* to which it is *R*-related’ and ‘Most *As* are *B*.’ Although many of these statements are meaningful, they, too, are neither strongly verifiable nor strongly falsifiable. Second, there are all sorts of statements that scientists make, positing the existence of unobservable things such as electrons, charge, and gravity, whose truth-value cannot be simply deduced from any set of observation statements. Rather, their justification lies in the explanation that they offer of observable events. Talk of strong verification and falsification does not do justice to a fundamental method of science – inference to the best explanation (cf. Soames, 2003, I: 280–282).

Weak Verification

The only answer is to retreat to a weaker notion of verification. In the weak sense, a statement is verifiable (and hence meaningful) if and only if, as Ayer put it, “it is possible for experience to render it probable” (1946: 12). Instead of seeing the important relation as deducibility *from* observation statements *to* the statement to be verified, the focus now is on deducibility *from* the statement to be verified *to* observation statements (which, if true, lend it empirical support). Ayer’s initial attempt at a definition may be formulated as follows: a synthetic statement *S* is weakly verifiable (and hence meaningful) if and only if *S*, either by itself or in conjunction with certain other premises, logically entails some observation statement *O* that is not entailed by those other premises alone. (Cf. Ayer, 1946: 15; Soames, 2003, I: 283.) On this definition universal generalizations, existential statements, more complex quantified statements, as well as hypothesized scientific explanations of observable events, all come out as meaningful, since observation statements can be deduced from them.

However, as it stands, this definition has the result that *all* statements come out as meaningful. For consider taking the single additional premise, ‘If *S* then *O*.’ From ‘*S*’ and ‘If *S* then *O*,’ ‘*O*’ clearly follows, without following from ‘If *S* then *O*’ alone. So the notion of verification formulated here is far too weak: the definition is satisfied by any statement whatever.

In response, Ayer distinguished between direct and indirect verifiability, restricted what ‘other premises’ are allowed, and formulated a more complex definition. (Cf. Ayer, 1946: 15–18.) But this too has been found to generate similar problems, with suitable choice of additional premises; and alternative formulations have also been found to be open to objections. (Cf. Church, 1949; Hempel, 1950; Soames, 2003, I: 284–291. But for a recent attempt at reformulation, see Wright, 1993, ch. 10.)

The Influence of Verificationism

If an adequate notion of verification cannot be formulated, then it undermines its role in a critique of metaphysics. One of its purposes had been to distinguish legitimate scientific statements from meaningless metaphysical statements – exemplified for the logical positivists in Heidegger’s famous remark that ‘Nothingness itself nothings’ (*Das Nichts selbst nichtet*) (cf. Carnap, 1932: § 5; Friedman, 2000: ch. 2). But it might well be argued that claims about the doctrine of verification itself are metaphysical statements whose status would be threatened if the doctrine were actually correct. Nevertheless, precise formulations aside, the general idea of verification has had enormous influence on subsequent philosophers. According to some, such as Carl Hempel and Quine, what was wrong was the focus on *individual* statements. Instead, they suggested, influenced by Pierre Duhem (1906), it is whole systems of statements that scientists seek to verify in their empirical activities. What has come to be called the Duhem-Quine thesis, that a scientific hypothesis cannot be tested in isolation, indicates the shift that there has since been from atomistic to holistic conceptions of verification. In the case of Quine, this was famously accompanied by rejection of the analytic/synthetic distinction that lay at the basis of logical positivism (Quine, 1951). But this rejection was only intended to purge empiricism of untenable doctrines, not to repudiate empiricism altogether. For Quine, philosophy and science are continuous, and even analytic statements are subject to revision in the light of empirical research.

Other philosophers who were also broadly sympathetic to verificationism took different approaches. In Dummett’s work, for example, in which holism is rejected (cf. 1991: ch. 10), the concern has been to develop a systematically articulated theory of meaning based on the notion of assertion-conditions rather than on the classical notion of truth-conditions. A verificationist rather than traditional conception of truth lies at the heart of Dummett’s project, and he has

seen in mathematical intuitionism the model for a semantics based on verificationist truth. Dummett has been led to reformulate many traditional debates, such as those concerning our knowledge of the past and future, in terms of the opposition between realism and antirealism, a reformulation clearly influenced by the verificationism of the logical positivists. (See, for example, Dummett, 1993, which starts by paying homage to Ayer. Cf. also Wright, 1993: chs. 9–10.) Despite the flaws in its original articulation, then, verificationism remains an active – though controversial – force in contemporary philosophy.

SUBJECT INDEX

NOTE

The index is arranged in set-out style with a maximum of three levels of heading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by T and F refer to Tables and Figures respectively. *vs.* indicates a comparison.

Cross-reference terms in italics are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space). Readers are also advised to refer to the end of each article for additional cross-references - not all of these cross-references have been included in the index cross-references.

This index is in letter-by-letter order, whereby hyphens and spaces within index headings are ignored in the alphabetization. Prefixes and terms in parentheses are excluded from the initial alphabetization.

To assist the user, specific languages have main entries in **bold**. To save space in the index, subjects specific to a language (e.g. morphology, syntax) are found as subentries under the language and not the subject. Cross references to the specific subjects (e.g. syntax, phonetics) are assumed and not explicit.
